31957. Sudden loss of bias, receive sensitivity, and transmit in TS-820S

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-19 22:56:25 UTC
From: ae5uu
Topic: 31957 Message: 31957

I have the following problem; sudden loss of bias, receive sensitivity, and transmit in my TS-820S.

All voltages are in spec:
14.0vdc
9.0vdc
3.3vdc
5.0vdc
-6.0vdc
All of the high voltages,including 900vdc, are correct at all test points, changing on transmit as per specification.

I have checked the following as well:

RL1 is OK
Connections to RL1 are OK
Tranceiver switch is OK
SG switch is OK
Fix Vox Q-13 is OK (although volume in the radio seems reduced)
The 14.0vdc at the Rectifier Unit is OK
Q-1 and Q-8 on the RF Unit are OK
R-6 on the Rectifier Unit is OK
No loose jumpers
No broken wires
No solder splashes
I want to check L-8 on the Coil Pack as per Kenwood instructions, but I can't find it; it is not on the schematic. L-1 through L-7 and L-9+ are on the schematic, just no L-8
Q-3 on the AF-AVR Unit is OK
All resistors in the Final Unit, HV unit, and the Rectifier Unit are OK

The only problem identified in testing is with Q-1 on the IF Unit. The schematic has to be incorrect. A connection from Q-1 to Q-4 is listed at 3.0vdc at Q-4 and 0.0vdc at Q-1. The actual value at Q-1 and Q-4 is 3.0vdc as it should be. At Q-1 the 14.5vdc voltage is correct. The common connection to Q-4, 3.0vdc, is OK. However the 3.0vdc (3.2vdc) voltage and the 2.0vdc (2.0vdc) voltage are not present.

Can anyone point me in the right direction on this issue?

Thanks,

AE5UU

I think this is going to be one of those agree to disagree discussions. Take a look at what one noted expert has to say about importance of screen grid regulation not only for linearity but for tube protection including how Collins did it with seperate high current supplies with choke input filters.

Hi
Switched "old faithful" on this morning and noticed that upon tune up, IP reading is rather low as is the bias voltage (about 35 ma instead of 60ma) on idle.
I suspect my HT rail is down but need a little guidance before I go changing the transformer in the rig !!! The HV voltage reading is only 450 volts ??? Is there anything else I need to check before moving on ? Other things I have noticed that the ALC reading is peaking much higher but the IP reading is low and would require an increase in clockwise motion of the carrier control to bring it up. I have carried out the tuning process but the maximum output power is only 20 watts. I hate HV and I do not really want to start "prodding" the transformer at this stage. Please help

regards
Will

further to the initial information written, I suspect one of the HV caps must have failed ? I guess a repair kit needs to be sought !
If anyone can further advise, I'd be mighty grateful

What a great feeling it is to fly solo !!!
Have worked out that the cause of the failure was indeed a HV capacitor !!! I have an old 830 chassis with some bits n bobs onboard from which I was able to rabbit the spares. Replaced the HV caps, HT reading now 900 volts and back on air again with no real injuries sustained. Sending off to my American cousin K4EAA for brand new HV caps and will carry out a more efficient repair when they arrive.
Case closed. Best wishes to one and all.....Will / GM0HKS

Will,
Your HV should run around 900VDC with no load from the finals. This may
vary up to as much as 940VDC. Sounds like you are on
the right track, your HV filter caps (one) have given up. You can order the
complete kit from Ken, K4EAA (www.k43aa.com). You
should replace the disc ceramic caps and resistors that are across the HV
cap terminals. Replace both caps, do not try and
keep one of the old ones. Just make notes and make sure you write down
where the wires go and make sure you wire it
back up the same way. You really need a DMM or VOM that can measure up to
1000VDC if you can get access to one
to check your voltage when done.

Regards

Chuck, KJ4GU

Will,
Also as a follow up from reading your email again.....

If you are NOT comfortable working with the High Voltage, find a ham in the area who can assist you.

You need to make sure the rig is unplugged from the wall, the HV Caps are discharged before working
on the unit.

You must ensure that the new caps are installed correctly (negative and positive sides) and that these
are wired in series.

When checking the high voltage, ALWAYS leave your left hand away from the chassis and table.

Use an alligator clip to connect the black lead to the chassis of the radio and your right hand only
for the red test lead.

The voltages in the Kenwood Hybrid is LETHAL. Please be careful, safety first.

With a HV reading of only 450V which is about 1/2 normal value, it is usually an indication of one of the HV smoothing Cap's has gone defective. You can get a replacement set from K4EAA or there are some of them on Ebay or you can go to Mouser or Digikey. Not sure what you mean by "HT" rail ? and or why you would need to change the transformer at this point?

Since Q4's Gate measures 3VDC but Q1's Gate 2 measures 0VDC (both Q4's Gate and Q1's Gate 2 leads are connected together and share the same 3VDC bias voltage), I would check continuity between Q4's Gate and Q1's Gate 2 first. I also would check the solder connections to Q1 leads, especially if Q1 has been replaced by a previous owner.

It's also possible that Q1 is bad, possibly an internal short, especially if Q1 has been replaced by a previous owner. MOSFET FETs are stable while in the circuit but are highly susceptible to static discharge damage outside a circuit if handled incorrectly.

I'm no expert on dual gate N-Channel (Q1) MOSFET FETs (Q1 is a 3SK35 Dual Gate N-Channel MOSFET FET). I've read up on them and I'm still learning.

Hi Chuck, Dennis & Jeramy,
thanks for the positive responses. It was indeed a failed HV cap that caused the issue. I have replaced them both and now the HV reading is back up at 900 volts and full output restored. With regard to the transformer Dennis; just over reaction and concern on my part. I took a chill pill and sat down to think about it; I ended up concluding that the caps should be the first to be replaced. Anyhow, its a great day as old faithful is back up and running like she always does; pity the bands are lousy here in the UK hi hi. Thanks again guys, I am deeply indebted to you all for your kind response. Very 73 all round.....Will

From: Russell Nilson
Topic: 31961 Message: 31969

Good morning Mike,

I was hoping that I would hear from you.

I did not make it clear enough in my last apparently; on the IF Unit, the connection from Q-1 to Q-4 has continuity, and thus they both read 3.0vdc. The error that I refer to is on the schematic that I have for the IF Unit that shows Q-4 to read 3.0vdc and Q-1 to read 0.0vdc; obviously a typo.

The NTE replacement for transistor 3SK35(GR) used at Q-1, Q-2, Q-3, and Q-18 is NTE-222. They are available at Mouser for over $12 each, so I haven't run out and bought new ones yet until I know just what (how many?) are bad, if indeed they are the problem at all.. I do have an old IF board that I pulled Q-1 from and replaced the one on my current board without effect. The troubleshooting section of the manual points a finger only at Q-1 on the IF board. Could this single transistor still being bad cause all of the problems that I have described?

Thanks for your help.

Since Q4's Gate measures 3VDC but Q1's Gate 2 measures 0VDC (both Q4's Gate and Q1's Gate 2 leads are connected together and share the same 3VDC bias voltage), I would check continuity between Q4's Gate and Q1's Gate 2 first. I also would check the solder connections to Q1 leads, especially if Q1 has been replaced by a previous owner.

It's also possible that Q1 is bad, possibly an internal short, especially if Q1 has been replaced by a previous owner. MOSFET FETs are stable while in the circuit but are highly susceptible to static discharge damage outside a circuit if handled incorrectly.

I'm no expert on dual gate N-Channel (Q1) MOSFET FETs (Q1 is a 3SK35 Dual Gate N-Channel MOSFET FET). I've read up on them and I'm still learning.

If Q1 is bad, not only would receive be affected but transmit (all modes) would also be affected. Q1 functions in both transmit and receive.

I guess I mis-read your statement when you talked about Q1s 3VDC (3.2VDC and 2VDC on Q1's Gate 1 and Source pins).

Yes, I agree, it appears the IF schematic voltage indications for Q4's Gate and Q1's Gate 2 are incorrect. Q1's Gate 2 should have 3VDC. This voltage will vary based on the AGC voltage produced in receive from an incoming signal. It also will vary depending on the ALC voltage produced during sideband transmission. The "AGL" line is common to both receive (AGC) and transmit (ALC) to control the gain of the IF amplifier.

If you have a signal generator you can apply a low level, 1mv or less, 8.830Mhz signal to the IF amplifier plug IF1 pin 1 and ground. This should produce a high S meter indication and AGC voltage at Gate 2 of Q1. Varying the signal level should cause the AGC voltage to rise and fall according to the signal generator's output level. This will tell if the IF unit is actually working properly or not.

If you take a look at the 6146B characteristic curves for plate current vs grid 1 voltages (RCA data sheet examined), you will see that for a fixed grid 1 voltage (say -10V) there is a plate current of about 200mA when the screen grid (grid 2) is held at 150V and this increases to 300mA when the screen grid is held at 200V. This means that if you set the bias on the tube with grid 1 to about 30-40mA while holding grid 2 to 175V and then you hold the same grid 1 voltage while modulating grid 2 from 150 to 200V you will see a variation in plate current from about 20mA to about 50mA. This variation causes a type of distortion by changing the operating point of the tube as a function of screen grid voltage. This is the problem with unstabilized screen grid voltages.

I am not sure how much variation occurs in the actual operation of the 6146B in SSB but if the screen grid is bouncing around by more than a few volts during speech modulation, the resulting plate current is being distorted. In practice, it does not seem to be much of an issue. Bypassing the screen grid for audio frequencies at the impedance of the grid circuit would probably negate or minimize any real distortion and I haven't checked if this is done on the hybrids or if they are just bypassed for RF.

Dennis, HT is for High Tension, a particularly British expression for High Voltage. We sometimes call the AC transmission lines from power generation stations, high tension lines for the same reason. The opposite to the HT rail is, of course, Earth. We on this side of the pond call it by its proper name, Ground. Now if I can just find my spanner I'll have a go at fixing something that's all bodged up!!

Cheers,
Larry, KS7J

31974. HV Caps voltage question

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-20 16:03:35 UTC
From: sv9dru
Topic: 31974 Message: 31974

Hi to all,
Just bought a TS-530s and found its HV caps neatly replaced by 4 new caps 68μF/400V each, mounted on a PCB with the associated bleeding resistors and ceramic caps. The PCB is very well installed in the place of the old HV caps.
It seems to work fine and I get about 900V indication in the rig's meter and about 50V sagging on voice peaks while operating SSB @ max output.

Do I need to be concerned about the 400V rating of these caps and replace them with 450-500V ones or just go by the old principle of "if it aint broken dont fix it" ??
Do I risk any sudden or catastrophic failure with these caps?

Any suggestions would be appreciated.

Bob- It probably is a minor problem and unless valid testing/measurng is done no way to really quantify it. I dont have a spectrum analyzer so no way for me to look at 3rd/5th order products under varying screen voltages. I also have no evidence that anyone who has recently lost a 6146 tube determined that it was due to exceeding screen grid dissipation.

It is not so much about "hearing" distortion, it is about IMD and what the adjacent stations on each side of your signal are "hearing". Tune across the bands and tune across some of the signals and see what is passing as "not a problem" in our crowded bands today.

I am sorry I brought it up. As I said in my original post I am of course interested in clean signal and extending the life of these old 6146 tubes that are available to us today. If lowering and regulating the screen voltage could accomplish both of those things , it would be pretty easy mod with the availability of simple mosfet shunt regulators.

It is pretty clear no one has seen any need to regulate the screen supplies in the hybrids so as you say it is a non-problem and I think best if we drop this thread.

If they were going to fail, it would be under receive conditions when the voltage across them is at a maximum. I would also have expected them to fail pretty soon after installation, which they evidently haven't.

The situation does represent a weak point and may give rise to problems in the future, but on the other hand the caps may last for many years.

Terry, very few people that are contributing to the "not a problem"
signals on the bands today are doing so because they are using hybrids
with no screen voltage regulation. This is a common problem, which is
caused in almost every case by the "all knobs fully clockwise" syndrome
which is so prevalent on the bands today.

Regulating screen voltage could possibly result in lower distortion
products, but it is highly doubtful that the decrease would be even
noticeable under today's over the air conditions.

It has been a fairly interesting topic for discussion from a technical
standpoint, but I hardly think that the results would be worth the effort !

73,
Jim

Hello Marinos,

Your post has what appears to contain a typographical error. What does the following mean?

"68µF"

What are the capacitance value and voltage rating of each capacitor and how are the 4 capacitors wired together on the PC board?

The HV supply in the TS-530 is a voltage doubling supply. The capacitors are wired in "series".

I would also have expected them to have failed in fairly short order.
They may have been hooked up in a series & parallel combination to get
a higher voltage rating. Is this maybe why they are mounted on a PC
board?

From: Jeramy Ross
Topic: 31874 Message: 31981

There seems to be two points driving this whole discussion:

1) Tube life. Given that there is still a fairly sigificant number of these rigs out there with their original PA tubes on the air gives a good indication of tube life with the existing SG supply. My 820 is a good example of this. I'm the third owner. Both past owners used it nearly daily. Dial/meter lamps have been replaced multiple times as has the driver. The original PA tubes are still going strong in spite of the unregulated SG supply. Lengthy tune ups, and improper tune ups are far more likely to damage/shorten the life of your PA tubes.

2) Linearity and distortion products in the PA. Again, given the well earned reputation of these rigs having great signals and audio on the air would go against this being a worry. Transmitted IMD reports on PSK, when using a properly adjusted rig, are typically excellent. Waterfall snapshot reports sent after a QSO also show a great clean signal. Similar positive experiences have been discussed with other hybrid owners who persue digital mode operation with their hybrids. Again, this is with the SG supply as is.

Persue your experimentation as you wish. No one is saying not to, but I doubt any improvement (if any) in the two areas mentioned will prove worth the time and effort nor be noticed on the air.

Respectfully,
Jeramy W5XTL

Larry,

How do you see the screens in the hybrids are modulated in the Kenwood hybrids? I would agree with you if the discussion was about DSB AM Plate Modulation where the screens and plates of the final tubes must be both modulated.

>
> If you take a look at the 6146B characteristic curves for plate current vs grid 1 voltages (RCA data sheet examined), you will see that for a fixed grid 1 voltage (say -10V) there is a plate current of about 200mA when the screen grid (grid 2) is held at 150V and this increases to 300mA when the screen grid is held at 200V. This means that if you set the bias on the tube with grid 1 to about 30-40mA while holding grid 2 to 175V and then you hold the same grid 1 voltage while modulating grid 2 from 150 to 200V you will see a variation in plate current from about 20mA to about 50mA. This variation causes a type of distortion by changing the operating point of the tube as a function of screen grid voltage. This is the problem with unstabilized screen grid voltages.
>
> I am not sure how much variation occurs in the actual operation of the 6146B in SSB but if the screen grid is bouncing around by more than a few volts during speech modulation, the resulting plate current is being distorted. In practice, it does not seem to be much of an issue. Bypassing the screen grid for audio frequencies at the impedance of the grid circuit would probably negate or minimize any real distortion and I haven't checked if this is done on the hybrids or if they are just bypassed for RF.

There is another point:
Satisfaction.
The knowledge that you have made a technical improvement no matter how insignificant they may be. The manufacturers obviously considered the small improvements (yet to be proved) were not worth the extra compnent cost, but that doesn't apply to the home experimenter.

The possibility of very slightly lower envelope distortion and slightly lowered tube dissipation are good enough excuses to mess about and experiment as I see it.

Amateur radio is supposed to be about this, after all. :)

Hi all,

I was pleasantly surprised to see all useful answers in this group! I wish you can direct me with my problem too.

I own TS-820S and for some reason (after a couple of years of no activity on the band), receiver receives signal on the bands OK. On 7 MHz for example however, display shows 5 MHz, at 14 MHz band it shows 12 MHz, on 21 MHz band shows 19 MHz. On 3.5 MHz and 1.8 MHz display shows correct frequency.

I did open the rig, checked connectors on counter mix & counter boards, have resoldered all vias there, checked the PLL unit's connectors, retuned coils for each band... but still not success. The only thing I did not get into it yet was coil pack.

Is it possible that my problem lays right there?

I am suspecting that within counter any of TTL chips is dead but how to identify it?

Thanks for your replies.

Yes, the hobby is about experimenting but without experience and knowledge, the "experimenting" can result in a radio that no longer works, barely works, or works improperly at best.

There are a lot of modifications that people have done to their radios. Some are good and some are not so good, and then there's the one that's make you scratch your head and say, "What on earth was this person thinking???".

Whether you or anyone else modifies their radio, is entirely up to the owner. We, as members, can only give you and others what we believe is the right way to go and/or whether the modification will provide any measurable benefit at all.

Anyone who is modifying their radios such as in this case, should have the test equipment available to perform "before" and "after" test in order to determine whether the modification actually improved performance, did nothing to improve performance, or actually made the radio's performance become significantly less. If these steps are not taken then there's no way to determine this modification actually improved performance or not.

Good luck.

Hello Jure,

Did you check the counter input levels (3-2, page 49 of the TS-820
service manual)? I have seen cases where it is barely enough on the
lower bands, and then below a workable threshold once you proceed up
the bands with the symptoms you describe.

Mike, I didn't say the screen was modulated, only that if it were, say by poor or no regulation on the screen supply which is the case in these types of hybrids, then some distortion would occur. This modulation can come from interaction between speech power peaks within the power transformer itself, for example. The transformer has dynamic characteristics (fluctuations on HV supply, e.g.) as a function of speech. This in turn causes fluctuations on the screen supply. Peaks of plate voltage during speech lulls will cause a change in secondary emission on the plate which get reflected in voltage fluctuations caused by current changes in the screen resistor, etc. These operating point fluctuations during actual speech is what give rise to the possibility of this type of distortion. You will notice that I originally stated that it does not seem to be a problem in practice so I doubt that from a practical point of view there is any more than a marginal improvement in these radios by a decent shunt regulator on the screen. The tradeoffs in performance versus cost are always engineering design decisions and once the design is good enough, it makes little sense to refine the design. Such is the case with the Kenwood hybrids, which were not only good enough, they were better than their peers.

Back in the late 50's and early 60's Collins and Boeing were heavily involved with distortion experiments in SSB speech intelligibility. These experiments were done to prove the effectiveness of SSB in adverse situations and had less to do with IMD and interference related issues, only intelligibility. I am certain that Collins designed a lot of their products for the amateur market based on some of these studies, but also considering the interference aspects of what their designs were doing. They also determined that their products achieved the level of good enough.

In practice, it does not seem to be much of an issue. Bypassing the screen grid for audio frequencies at the impedance of the grid circuit would probably negate or minimize any real distortion and I haven't checked if this is done on the hybrids or if they are just bypassed for RF.

Thanks for the suggestions, just for the typo error, the caps are 2x 68uf 400V in parallel and tin series with the other pair of identical caps. That would be equivalent to 136uf 400V + 136uf 400V.

Have found some replacement caps of 100uf 450V each and plan to use 4 in place of the above just to increase their voltage rating. That would give 200uf + 200uf at 450V.
Any thoughts on on using double the capacity from the original 100+100 uf caps?

Marinos.

Thanks for the suggestions and sorry for the typo error, I had the Greek letter "m" in front of the Farad which the server did not like too much.
So the caps are 68uF @ 400V each. Wired in parallel for each pair for a total of 136uF the pair and connected in series with the other pair.

Theoretically that should be equivalent to 136uF @ 400V X 2 instead of 100uF @ 500V X2 in the stock Ts530s.
My main concern is the voltage rating as the higher capacitance should be an advantage and not a risk.

I have located and bought some 100uF @ 450V caps from ebay which will fit at the existing PCB for a replacement, just to be on the safe side. With those I will have 200uF @ 450V X2 for the HI voltage doubling circuit.

Marinos.

Hi Marinos,

Unfortunately the total working voltage is too low for the HV supply. The typical standby voltage of the HV supply is 150VDC higher than the capacitor group you have.

You are correct, the total capacitance is 136ufd but the total working voltage is only "800VDC". Although the capacitors may have a 10% to 20% tolerance rating, a total working voltage of 800VDC is not nearly enough to safely use those capacitors in the HV supply. Therefore, I recommend you do not use the four 68ufd 400VDC capacitor combination as replacements for the original HV filter capacitors. Just because they haven't failed doesn't mean they will not fail. I'm sure some folks will say they have been using similar combinations without any problems but that's no indication that it's safe to use this combination.

Having said, that whether you continue to use this unsafe combination or not is entirely up to you. I can only recommend that you don't use them.

Jeramy is right. The "88" and "455" indicate the IF frequency the filter's designed for.

This and additional answers/information pertaining to crystal filters used in the 830 are located in the 830 operator's manual, "Section 5. Optional Accessories" and in the 830 service manual's "Circuit Description" sections.

I would say you could fit the 450v 200uF caps in there, as long as the extra surge current didn't put the rectifiers at risk.

When you first fit these new caps assuming you do, this is what I would do first to ensure the dielectric was properly formed and not presenting too high a leakage current:

Switch on the rig for a few seconds then off again for 15 seconds or so. Do this a few times then leave it on for half a minute. SAFELY have a feel of the case of the caps (switched off and discharged) to see if any one is running warm. if not, power up the rig for a few minutes and do the same. If the temp of the caps is still cool, you should be OK.

Of course, should a cap overheat catastrophically you'll hear about it!

Points well taken, and I would be more than happy to return the HV caps to their original configuration using one of the recommended replacement pairs 120uf at 500v.
Unfortunately the previous owner, before installing the new PCB with the 4 68uf caps discarded the original supporting hardware so no way of installing the original caps with no rings etc...
Anyway, will try those 100uf at 450V x 4 and post the results.
If anything, they should be safer to use than the 400V ones already present in the rig now.

Thanks for the advice guys,
73

I agree with that statement! In industry, the normal thing has always been to use capacitors with a 100% margin on expected voltage vs. the value given on the capacitor. For a 800 volt working voltage, caps of 1500-1600 volts would probably be used. YMMV, but I would certainly use higher voltage rated caps!

Yes, you're right John. I wrote the wrong values down when I calculated the total capacitance.

If four 100ufd 450VDC capacitors were used in the same series parallel configuration, the total capacitance would be "100ufd" at 900VDC.

First pair of 100ufd in parallel simply add together
100 + 100 = 200 at 450VDC (C1)

Second pair of 100ufd in parallel, same, add together
100 + 100 = 200 at 450VDC (C2)

then use the capacitor's wired in series formula

C1 x C2 / C1 + C2

results in the total capacitance of;

200 x 200 / 200 + 200 = 100ufd at 950VDC

My last response ending saying

"200 x 200 / 200 + 200 = 100ufd at 950VD"

That should be "900VDC", not "950VDC"

sorry about that.

Hi,

It's nice to see that even with some disagreement (regarding the value of this regulation) no smoke, no flames. The point about getting hard data is a good one and if somebody wants to measure the before and after performance that would be worthwhile. Especially if the procedures and results are posted so everybody has access to it and won't have to reinvent the wheel. Sometimes unexpected results are found that are completely unrelated to what the experimenter thought he was looking for.

In this late phase of my amateur career I am trying to acquire some test and measurement gear (actually more of it) so that I can investigate a number of myths and seat of the pants claims. I would like to see some hard numbers and then publish the steps, results, and conclusions. Is a Pullen mixer really superior? If so, how? Maybe under some conditions. What conditions? That sort of thing.

Go for it. I can't imagine anything worse will ever happen than the power FET will turn into popcorn and lose the screen voltage. The transmitter will simply stop.

73,

Bill KU8H

I agree. Nothing is achieved by flames and disrespecting others. We are all here to learn and pass on what we know. The more we discuss topics the more we learn and pass on our knowledge. That is why I have been a member of this group for a long time and why I will continue to be a member. There is always something new to learn.

32004. Re: HV Caps voltage question

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-22 05:45:45 UTC
From: sv9dru
Topic: 31980 Message: 32004

There is one more detail overlooked Mike. Since these caps are used in a voltage doubler configuration, they are acting as individual pairs rather than as one cap consistent of both pairs connected in series.
Each pair of parallel caps is being charged during an opposite half cycle of the rectified AC from the HV 2x400V secondary of the transformer, so each pair is acting by "itself" even though they seem to be connected in series.
So in this particular circuit there is 200uf at 450V (100+100 in parallel) used by each half of the full wave voltage doubler.

What is important though for both pairs is to withstand at least 400V each or at least 800V for their in series combination in order to safely handle the voltages present. Of course, one has to use a capacitor having a "comfortably" higher voltage rating than the max voltage being present in the circuit, in order to be on the safe side.
It makes sense what Jim AG3Y is saying about the industry standard in the voltage rating of caps, and that is probably the reason why the 400V ones present in my Ts530 have not exploded yet !!!

If we had 4 caps of the same capacitance (and voltage rating) connected in parallel and series 100+100 in series with another 100+100 pair, the total capacitance should be the same as 200+200 in series or 100uf total.

32005. TS-520 vs TS-520s

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-22 09:08:13 UTC
From: on5py
Topic: 32005 Message: 32005

Hi group,

Just bought a 1976 vintage TS-520 that, after switch spraying, works very well.

I have both user's and service manual.

I have them for the following version, the TS-520s, and I noticed that, beside major differences - 160 meter, etc.. - there are also many minor mods aiming to better strong-signal performance.

Hence my question : is it worth tracing them and implementing them in the bare 520 ???

Any comment is VERY welcome !

Thanks & 73 - Daniel, ON5PY

32006. power supply

OK..... well Mike (nor anyone else) answered this question... so...

One thing that springs to mind is that I did change the RF board that was faulty in my TS-830s for one from Bob Mansker (which he and I of course assume work ok) but thinking back, it's the time that my Power out was reduced to around 60-W..... So, Mike et all (if you could respond I'd appreciate it)...

Is the RF board a good place to start looking and if so, around what are?

Thanks
Chris, ZL1CDP

From: Chris Parnell
Topic: 31926 Message: 32008

Is the RF board a good place to start looking and if so, around what area

is what it was meant to read.

i fixed it. it was a semi loose transistor on the af board.

now its fine and dandy.

Chris--Are you saying you cannot load to any higher than 150ma IP?

If all 6146 tube voltages are normal, that sounds like drive to me. TP-4 and DRV on RF board are good place to look with your RF VTVM. Terry

Subject: Fwd: [TS-520_820_530_830] Re: Speech Processor alignment

OK..... well Mike (nor anyone else) answered this question... so...

One thing that springs to mind is that I did change the RF board that was faulty in my TS-830s for one from Bob Mansker (which he and I of course assume work ok) but thinking back, it's the time that my Power out was reduced to around 60-W..... So, Mike et all (if you could respond I'd appreciate it)...

Is the RF board a good place to start looking and if so, around what are?

Thanks
Chris, ZL1CDP

<snip>

Note: I did NOT say that caps that have a 400v rating are good for 800 volts. I'm not sure if you understood it that way, or not. I meant that in industry, if the engineers expected to see 400 volts at a certain point in the circuit, they would specify that caps good for at least 800 volts would be used in that place ! There is quite a bit of difference in the meaning, and that is what I intended to point out.

I would not think that the circuit as I understand it to be constructed would be very safe. In addition to the series-parallel version of the caps, equalizing resistors, and spike suppression capacitors should be utilized , in order to keep the voltage drops across each cap under control.

And BTW, this "industry" I am talking about would typically be the broadcast industry, or the military, where cost is much less of a factor than it is in the consumer industry. That would be reasons why corners would not tend to be cut quite as much as they would be in the consumer trade!

Hope this clarifies what I was trying to say.

73, Jim AG3Y

Hi Chris,

I agree with Terry. Knowing that you replaced the RF board and since RF drive is produced on the RF board, it stands to reason the RF board is the place to start.

I do not believe, at this point, the problem exists elsewhere. This does not mean the problem could be elsewhere after you do some troubleshooting. Don't guess because more than likely you will be wrong. Think about what the problem is and if necessary, review the 830 operators and service manual's "Circuit Description" sections to refresh your memory on how the 830 processes both receive and transmit signals. Again, don't guess.

Review the 830 service manual transmit Level Diagram on page 44. Compare the levels in your 830 to the levels in the 830 service manual. This will give you an idea of what's going on in the 830 as far as transmit levels are concerned. Don't forget there are some common circuit that affect both transmit and receive.

If you have not yet done so, measure the voltages on the RF board, especially on the driver tube. Use the 830 high resolution schematic I sent you. The voltages in question are the red voltages. Compare your voltages to the high resolution schematic voltages.

73s
Mike
W5RKL

32013. Re: HV Caps voltage question

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-22 13:33:37 UTC
From: sv9dru
Topic: 31980 Message: 32013

Yes indeed I did misunderstood that statement Jim. Thanks for the correction.

My 520 has one and I ran mobile with it for a few years back in the 70's.
I have not used DC power for over 30 years so I may be willing to remove it and ship for the right price.
What is your callsign>>??.

I am looking for a dc supply that bolts on the back of the ts-520.
If anyone has one please let me know .

Daniel,

Good to hear that just a bit of "spraying" got you going. Even being "minor mods" as you stated, from my experience it's been more trouble than it's worth. My reasons are: If you have to remove any board...better have a good way to unwrap and then re-wrap all those wires. I guarantee... YOU WILL BREAK SOME even with the proper tool. These wires have been in the same position for...what....35+ years! I just have found it not worth my time if the rig works well...aligned and tuned correctly...but I guess that's what this hobby is all about...but..also be aware of those carbon tuning slugs on the ANT/MIX/XMIT boards.....they are fragile...and will crack/break if you look at them wrong! Find a good non-contaminating lube that will not melt or swell plastic or turn "gooey." I have used a synthetic lube with "teflon" and a needle point applicator...and have ONLY broken 3! They are very hard to find...well....good luck.....

Subject: [TS-520_820_530_830] TS-520 vs TS-520s

Hi group,

Just bought a 1976 vintage TS-520 that, after switch spraying, works very well.

I have both user's and service manual.

I have them for the following version, the TS-520s, and I noticed that, beside major differences - 160 meter, etc.. - there are also many minor mods aiming to better strong-signal performance.

Hence my question : is it worth tracing them and implementing them in the bare 520 ???

Any comment is VERY welcome !

Thanks & 73 - Daniel, ON5PY

I believe I should mention here that wire-wrap wires are NOT MEANT to be re-wrapped once the original wrap is un-done. You should always solder the re-wrapped connection, as it is no longer "gas-tight" and will eventually oxidize and possibly form a bad connection that will be the devil to find!

Just the "word to the wise", from one who did wire-wrap for years !

32020. TS-530SP QUESTION

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-22 19:54:51 UTC
From: Fun
Topic: 32020 Message: 32020

I have an opportunity to purchase(in person) Kenwood TS-530SP. I will be able to test/operate it prior to purchase.

The following describes the condition of the rig:
1. When was the last time the rig was in operation?

Maybe 18 years? I turned it on last nite and heard sounds from the speaker.

2. What does the rig come with? mike , cord , etc.

See mike and cord in the photo I sent to you.

3. Cosmetic condition - clean or marred(scratches)?

Clean.

4. Operating manuals/instructions, original box included?

Instruction manual - I sent photo - we never got a box from the man who sold to us.

Since the TS-530 is over 20 years old, outside of possible replacement of the PA tubes, what other technical concerns/problems might
be anticipated. I am aware that this rig is a hybrid with tubes in the power output where you would have to have to adjust the Load,
Plate , and Drive. I intend to read the manual before examining the rig.
Thanks, 73 , KC2TBA, Fun

Hey Fun,

Most of the time the HV(high voltage) capacitors may be "sagging" a bit in supplying full voltage for full output...look for about a minimum of 780(key down) or so volts..900 or so at "idle"...you can check with the front panel meter...use the meter selector switch.."HV" and flip the send switch...do this with a dummy load/antenna connected as you should check this also after you "tune-up" to see how much voltage you have. Replacement cap. kits are readily available. If rig suffers from "high plate current" and low power output the cathode resistors can be at fault....a few cents to fix...and some time...usually caused by excessive time "tuning-up." Output should be nominal of 100W(slightly lower on the higher freq bands) with around 200-250mA of plate current. Don't go just replacing the PA tubes 'cause they are old...check for proper output/function first. I have only had to replace 2 sets of PA tubes on "other rigs." I still have an 820S with
the original S2001A's PA tubes...still going strong. These rigs are pretty tough...but do get abused. Also, you might notice some "scratchy" pots...easy to clean with some good tuner cleaner/lube and "canned air." Maybe you can use the antenna to see if it actually does receive signals...and not just "noise." If you decide to buy it..get it home...read the manual(s) to get used to tuning them up. You may also want to have some more fun by removing all the connectors one by one and clean them up (connector and board side)...they do get oxidized and can cause signal flow problems...do this by reconnecting/disconnecting several times with some cleaner wetting the pins. Good luck.....

I know everyone recommends the "connector clean and wipe" and it is probably needed, but be darned carefully pulling connectors off to clean them.

Try not to rock them side to side as you apply upward pressure. If you have to rock them try to do it gently end to end.

It is very easy to crack a foil pad from its trace and not even see it. Can give you fits troubleshooting. Then you are in to making jumpers and trying to extend solder flows to bridge breaks and all those kinds of cobble jobs to save the board. Just my experience. Terry -K9TW

Hi Terry,

The voltages at the tubes seem a little low from memory, I will measure them again tonight. The Driver tube voltages (from memory) looked ok though... but again, I will double check tonight.

Terry, the situation is that if I tune for maximum power out (about 60 - 70 W), then the IP is around 140-160mA.
If I adjust for 225mA my output power is almost non existent, hence me wanting to get this thing resolved.

Cheers
Chris

32024. Re: Speech Processor alignment

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-23 01:56:15 UTC
From: Terry Wagoner
Topic: 31926 Message: 32024

Chris--I just tuned up to 225ma IP on my spare TS-830 on 14.200. Approx 105 watts on Drake W4 wattmeter into Heath cantenna dummy load at 225ma IP.

I then measured drive on RF board using a Heath IM-18 VTVM and a Heath 309C RF probe.

1. At TP-4 g1 of driver tube the voltage was 3.1 volts (2.1).

2. At output of driver tube DRV)at back lug of variable capacitor VC-3 (nearest PA cage) voltage was 66.0 volts (77.5).

See Page 44 of service manual for test conditions. The Heath VTVM is not true rms but close enough for this testing. Terry

32025. Need help on 520S Ant. bd, Mixer bd. & Drive bd..

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-23 02:54:43 UTC
From: Bob
Topic: 32025 Message: 32025

I have a fellow Ham in Australia that wants the following boards:
Ant Coil bd..... X44-1070-00 (I have a X44-1170-00)
Mixer Coil bd..... X44-1080-00 (I have a X44-1180-00)
Drive Coil bd..... X44-1090-00 (I have a X44-1190-00)

My 520S serial is 651215
I wander if he may have an earlier 520S & Kenwood came out with the ones I have...

Are the above boards the same?_____
Thanks in advance.
Bob

32026. Re: [TS-520_820_530_830] Re: Speech Processor alignment

Topic: 31926 Message: 32026

Thanks Terry,

I will check these on mine when I get home.

Cheers
Chris

Fun & Terry,

Good point about the connectors...forgot that one...as I use one finger to hold down the board while I'm trying to remove the connector...I usually use a small "needle-nose" tool to loosen one end then the other while GENTLY pulling up. As Terry said...BE CAREFUL good luck.....

I know everyone recommends the "connector clean and wipe" and it is probably needed, but be darned carefully pulling connectors off to clean them.

Try not to rock them side to side as you apply upward pressure. If you have to rock them try to do it gently end to end.

It is very easy to crack a foil pad from its trace and not even see it. Can give you fits troubleshooting. Then you are in to making jumpers and trying to extend solder flows to bridge breaks and all those kinds of cobble jobs to save the board. Just my experience. Terry -K9TW

Subject: Re: [TS-520_820_530_830] TS-530SP QUESTION

Hey Fun,

Most of the time the HV(high voltage) capacitors may be "sagging" a bit in supplying full voltage for full output...look for about a minimum of 780(key down) or so volts..900 or so at "idle"...you can check with the front panel meter...use the meter selector switch.."HV" and flip the send switch...do this with a dummy load/antenna connected as you should check this also after you "tune-up" to see how much voltage you have. Replacement cap. kits are readily available. If rig suffers from "high plate current" and low power output the cathode resistors can be at fault....a few cents to fix...and some time...usually caused by excessive time "tuning-up." Output should be nominal of 100W(slightly lower on the higher freq bands) with around 200-250mA of plate current. Don't go just replacing the PA tubes 'cause they are old...check for proper output/function first. I have only had to replace 2 sets of PA tubes on

"other rigs." I still have an 820S with
the original S2001A's PA tubes...still going strong. These rigs are pretty
tough...but do get abused. Also, you might notice some "scratchy" pots...easy to
clean with some good tuner cleaner/lube and "canned air." Maybe you can use the
antenna to see if it actually does receive signals...and not just "noise." If
you decide to buy it..get it home...read the manual(s) to get used to tuning
them up. You may also want to have some more fun by removing all the connectors
one by one and clean them up (connector and board side)...they do get oxidized
and can cause signal flow problems...do this by reconnecting/disconnecting
several times with some cleaner wetting the pins. Good
luck.....

Subject: [TS-520_820_530_830] TS-530SP QUESTION

I have an opportunity to purchase(in person) Kenwood TS-530SP. I will be able to
test/operate it prior to purchase.

The following describes the condition of the rig:
1. When was the last time the rig was in operation?

Maybe 18 years? I turned it on last nite and heard sounds from the speaker.

2. What does the rig come with? mike , cord , etc.

See mike and cord in the photo I sent to you.

3. Cosmetic condition - clean or marred(scratches)?

Clean.

4. Operating manuals/instructions, original box included?

Instruction manual - I sent photo - we never got a box from the man who sold to
us.

Since the TS-530 is over 20 years old, outside of possible replacement of the PA
tubes, what other technical concerns/problems might
be anticipated. I am aware that this rig is a hybrid with tubes in the power
output where you would have to have to adjust the Load,
Plate , and Drive. I intend to read the manual before examining the rig.
Thanks, 73 , KC2TBA, Fun

Hi Terry,

I am seeing nothing like that on my RF board! - I see +12.0V DC at TP-4 in RX and at the "back lug" of VC-3 (which I assume is the one with the small cap attached to it that goes to VC-2?) has "variable" readings in RX - I occasionally see +38V for split second, then it drops to zero (or close to zero), with the reading varying around a bit.

Sounds like a bad connection / earth maybe? I hope I am reading your test procedures correctly

Unfortunately, in the copy of the service manual I have, page 44 is the VFO-230 schematic.

Cheers
Chris

From: Chris Parnell
Topic: 31926 Message: 32029

Hi Mike

Thanks for this.. I will do some voltage measurements and come back to you.

Cheers
Chris

> Hi Chris,
>
> I agree with Terry. Knowing that you replaced the RF board and since RF drive is produced on the RF board, it stands to reason the RF board is the place to start.
>
> I do not believe, at this point, the problem exists elsewhere. This does not mean the problem could be elsewhere after you do some troubleshooting. Don't guess because more than likely you will be wrong. Think about what the problem is and if necessary, review the 830 operators and service manual's "Circuit Description" sections to refresh your memory on how the 830 processes both receive and transmit signals. Again, don't guess.
>
> Review the 830 service manual transmit Level Diagram on page 44. Compare the levels in your 830 to the levels in the 830 service manual. This will give you an idea of what's going on in the 830 as far as transmit levels are concerned. Don't forget there are some common circuit that affect both transmit and receive.
>
> If you have not yet done so, measure the voltages on the RF board, especially on the driver tube. Use the 830 high resolution schematic I sent you. The voltages in question are the red voltages. Compare your voltages to the high resolution schematic voltages.

Topic: 32020 Message: 32030

Thanks for replies , I do plan to bring my buddipole antenna to test the TS-530SP, current owner has been out of the hobby for 18+ years, no antenna at sellers QTH. Will have my FT857 in my car to see if it the kenwood rig transmits and receives.

Owners stated it makes sounds when plugged in(hope to hear stations when connected to BP antenna). I am kind of hesitant to transmit not knowing what the settings for driver, plate and load parameters are after long period of inactivity. I guess the rig will have to be tuned (with owners help) or go by the manual. I would have to go slow as I am not up to speed with operating hybrid rigs.

Meanwhile , I will reading the manual and feeding my brain with info from the web.

Thx again,73, Fun Leung ,KC2TBA

Hi Joe,
I often see funny characters in posts (not just yours and not just in this group. For instance, in your post I see
quote
current"Â and
unquote

I often wonder what causes this, I usually blame Windows and/or Intenet Explorer!

Chris--The page you need is the Level Diagram page. You can view it on Gordons N6WK website. The readings in question are RF at 14.2 Mhz and not DC voltages in RX mode.

You need an RF probe. Yes the lug on VC-2 has a small cap soldered to it. I went there for conveniencetto keep RF probe ground lead short and be able to move probe tip from TP-4 to DRV, but you can go to Blue wire on foil side of tube socket board as well.

If you dont have a high Z meter and rf probe you can use an oscilloscope (20mhz bandwidth or greater) and 10/1 probe.

You will be taking the RF drive level readings with SG off, in CW mode, with ALC level set with Carrier Level, and Standby switched to Send.

You have to have some level of drive to get 70 watts out at 160ma.

If your drive level readings and 6146 tube voltages are good then I would try swapping out tubes again and I would very carefully try to read anode voltage on each tube under the plastic plate caps. I once had a very high resistance connection from top of plate choke at the back tube and best I could get out was slightly more than half power. I found it by using insulated tuning tool and gently pushing on plate cap and parasitic choke and could see output power move around. Turns out the anode wire coming out of glass envelop was not soldered well to top of silver anode cap on the tube.

Typically with low output power and high plate current it means one of two things 1. Tank not tuned to resonance or 2. Not getting sufficient RF voltage swings at the final tube plates. (low drive). Good luck - Terry K9TW

Subject: Re: [TS-520_820_530_830] Re: Speech Processor alignment

Hi Terry,

I am seeing nothing like that on my RF board! - I see +12.0V DC at TP-4 in RX and at the "back lug" of VC-3 (which I assume is the one with the small cap attached to it that goes to VC-2?) has "variable" readings in RX - I occasionally see +38V for split second, then it drops to zero (or close to zero), with the reading varying around a bit.

Sounds like a bad connection / earth maybe? I hope I am reading your test procedures correctly

Unfortunately, in the copy of the service manual I have, page 44 is the VFO-230 schematic.

Cheers
Chris

Chris--TYPO--VC-2 should be VC-3 sorry. Also, you should not have read any dc voltage at VC-3 DRV blue wire. Not sure why you saw erratic 38 volts? C1 at 6146 grids should block tube -100 vdc bias and C29 from plate of 12BY7 should block plate voltage. If you do have 38 volts on DRV blue wire in RX mode it appears bad cap which would be rare? Terry

Subject: Re: [TS-520_820_530_830] Re: Speech Processor alignment

Chris--The page you need is the Level Diagram page. You can view it on Gordons N6WK website. The readings in question are RF at 14.2 Mhz and not DC voltages in

RX mode.

You need an RF probe. Yes the lug on VC-2 has a small cap soldered to it. I went

there for conveniencetto keep RF probe ground lead short and be able to move probe tip from TP-4 to DRV, but you can go to Blue wire on foil side of tube socket board as well.

If you dont have a high Z meter and rf probe you can use an oscilloscope (20mhz bandwidth or greater) and 10/1 probe.

You will be taking the RF drive level readings with SG off, in CW mode, with ALC

level set with Carrier Level, and Standby switched to Send.

You have to have some level of drive to get 70 watts out at 160ma.

If your drive level readings and 6146 tube voltages are good then I would try swapping out tubes again and I would very carefully try to read anode voltage on

each tube under the plastic plate caps. I once had a very high resistance connection from top of plate choke at the back tube and best I could get out was

slightly more than half power. I found it by using insulated tuning tool and gently pushing on plate cap and parasitic choke and could see output power move around. Turns out the anode wire coming out of glass envelop was not soldered well to top of silver anode cap on the tube.

Typically with low output power and high plate current it means one of two things 1. Tank not tuned to resonance or 2. Not getting sufficient RF voltage swings at the final tube plates. (low drive). Good luck - Terry K9TW

Subject: Re: [TS-520_820_530_830] Re: Speech Processor alignment

Hi Terry,

I am seeing nothing like that on my RF board! - I see +12.0V DC at TP-4 in RX and at the "back lug" of VC-3 (which I assume is the one with the small cap attached to it that goes to VC-2?) has "variable" readings in RX - I occasionally see +38V for split second, then it drops to zero (or close to zero), with the reading varying around a bit.

Sounds like a bad connection / earth maybe? I hope I am reading your test procedures correctly

Unfortunately, in the copy of the service manual I have, page 44 is the VFO-230 schematic.

Cheers
Chris

32034. Re: [TS-520_820_530_830] Re: Speech Processor alignment

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-23 11:50:16 UTC
From: Terry Wagoner
Topic: 31926 Message: 32034

Chris--You mentioned "bad earth". When you measure the RF drive levels try to keep meter or scope ground lead short. Ground post TP-G is provided on the RF board for this. Do not connect meter or scope ground lead to the frames of the three VC variable caps as they are floating above ground. OK to use chassis "earth" (ground) if you cant get on TP-G.

I suppose we will be talking about "aerials" next!

The small cap on VC-3 is C77 which is part of the neutralizing circuit. Terry

Subject: Re: [TS-520_820_530_830] Re: Speech Processor alignment

Chris--TYPO--VC-2 should be VC-3 sorry. Also, you should not have read any dc voltage at VC-3 DRV blue wire. Not sure why you saw erratic 38 volts? C1 at 6146

grids should block tube -100 vdc bias and C29 from plate of 12BY7 should block plate voltage. If you do have 38 volts on DRV blue wire in RX mode it appears bad cap which would be rare? Terry

Subject: Re: [TS-520_820_530_830] Re: Speech Processor alignment

Chris--The page you need is the Level Diagram page. You can view it on Gordons N6WK website. The readings in question are RF at 14.2 Mhz and not DC voltages in

RX mode.

You need an RF probe. Yes the lug on VC-2 has a small cap soldered to it. I went

there for conveniencetto keep RF probe ground lead short and be able to move probe tip from TP-4 to DRV, but you can go to Blue wire on foil side of tube socket board as well.

If you dont have a high Z meter and rf probe you can use an oscilloscope (20mhz bandwidth or greater) and 10/1 probe.

You will be taking the RF drive level readings with SG off, in CW mode, with ALC

level set with Carrier Level, and Standby switched to Send.

You have to have some level of drive to get 70 watts out at 160ma.

If your drive level readings and 6146 tube voltages are good then I would try swapping out tubes again and I would very carefully try to read anode voltage on

each tube under the plastic plate caps. I once had a very high resistance connection from top of plate choke at the back tube and best I could get out was

slightly more than half power. I found it by using insulated tuning tool and gently pushing on plate cap and parasitic choke and could see output power move around. Turns out the anode wire coming out of glass envelop was not soldered well to top of silver anode cap on the tube.

Typically with low output power and high plate current it means one of two things 1. Tank not tuned to resonance or 2. Not getting sufficient RF voltage swings at the final tube plates. (low drive). Good luck - Terry K9TW

Subject: Re: [TS-520_820_530_830] Re: Speech Processor alignment

Hi Terry,

I am seeing nothing like that on my RF board! - I see +12.0V DC at TP-4 in RX and at the "back lug" of VC-3 (which I assume is the one with the small cap attached to it that goes to VC-2?) has "variable" readings in RX - I occasionally see +38V for split second, then it drops to zero (or close to zero), with the reading varying around a bit.

Sounds like a bad connection / earth maybe? I hope I am reading your test procedures correctly

Unfortunately, in the copy of the service manual I have, page 44 is the VFO-230 schematic.

Cheers
Chris

32035. Re: Speech Processor alignment

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-23 12:47:20 UTC
From: w5rkl
Topic: 31926 Message: 32035

The transmit mixer's RF signal level at TP4 should be approximately 2.4 volt rms.

The RF signal level at the output of the driver tube should be approximately 77.5 volts rms.

The driver's RF signal level at the grids of the final tubes should be approximately 53.3 volts rms.

The "TIF" signal from the IF Unit, RF unit plug 7 pin 2, should have an approximately RF signal level of 12.4mv rms.

These RF signal level voltages came from the 830 service manual's Level Diagram on page 44. Chris you said page 44 in your 830 service manual is the remote VFO. Page 45 in the 830 service manual is the remote VFO-230. You may be confusing that page with page 44.

The setup is what Terry said, frequency 14.2Mhz, SG switch OFF, and the CAR control is adjusted for maximum ALC scale indication. Connection grounds should be as close to the RF probe or scope connection as possible.

I hope this helps.

Topic: 32005 Message: 32036

Hi Daniel,

I can't speak to the 520 directly as I have something different - 599 Twins. Mine are plain. The D models have some differences. In mine the effort to "update" is not worth the trouble.

I have a Heathkit DX-100. There is a B model with additional features. Heath also sold the TX-1 Apache and there are even more improvements in that model. You can see the evolutionary line. My plain DX-100 has some of the later features added to it. They were simple to do and there were no structural modifications made. Those mods were worthwhile.

If you study the differences between your plain 520 and the s model so that you understand what would have to be done vs the expected benefit you might decide to do some of them and not others. Something else to consider is how such changes might affect the resale value of your radio. In almost all cases the value will decrease. If you do make changes please document them and attach a copy of the document inside the radio so the next owner has a chance to keep the radio in service.

73,

Bill KU8H

Maybe what is being referred to here is all the arrows and reposted replies in Chris's thread about the speech processor. I understand it is nice to be able to reference the earlier posts in reading what is written today, but the thread has gotten so long that it takes a matter of minutes just to find the end of each post. They ARE hard to read with all the arrows in them, too. It might be time to truncate some of the old, early replies off your answers.

Thanks,
Roy Kersey

Topic: 32040 Message: 32040

Hello All,

I am still a ways from getting on the air with my TS-830S. I have a nice old Shure mike for it, but I was recently thinking that, with my hearing problems, I might do better with a headset that would seal out extraneous noise and allow me to use the direct connection afforded by the voice coil switch on my hearing aids. I see that at eham there are several cheap headsets that are touted as being pretty good. Does anyone have some recommendations for a headset that would work well with the TS-830S?

Hello again,

'Nother question. When I hauled out the TS-830S the other day to get another look at it, I noticed that it is a "Gold" model with the bronze colored nameplate. I found a picture of the cover removed, showing two filters, but how would I find out whether this unit still has all four filters installed? Do I have to remove the board and look on the other side? Or is there a simple on the air test that would tell me?

TIA & 73,

32042. DRIVE COIL ADJUSTMENT

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-23 16:26:08 UTC
From: AL
Topic: 32042 Message: 32042

Hi there
In the ts-830 service manual, Adjustments, Nº18, Generator, Drive coil adjustment, one of the "conditions" call for CAR VR (I think it is the front panel Car Control)"CENTERED".
If I do so, following the manual procedure; I got ALC readings out of the meter scale in almost all bands. It is suppose to go for the "Max. ALC meter reading", to be able to see the maximum reading I have to lower the CAR control, and in this case I am not in the "conditions" the manual ask for.
I haven´t adjust any drive coil yet because I don´t know if the levels I am getting now are ok and If it is correct to lower the CAR level to see the maximum. Could anyone give some advice on this?

Hi Roy,

Do you have the TS-830 operators manual? If not then I recommend downloading it from Gordon's website

www.n6wk.com/kenwood/

Go to page 24 Section 5.2, Installing Accessories, for instructions on installing/connecting the filters. The filters are located on the IF board, with top cover off, the IF board is the PC board on the left front.

Al,
It is the DRIVE control that is supposed to be centered when you adjust the drive coils.
Also make sure you do the drive coil adjustments at the correct frequency in the service manual. If the ALC is too high, you turn down the carrier control.

Dont be slow in dipping the plate current as you can damage things with long periods of untuned transmission ! Do not let the plate current stay anywhere over 250 MA for more than a few seconds

Subject: [TS-520_820_530_830] Re: TS-530SP QUESTION

Thanks for replies , I do plan to bring my buddipole antenna to test the TS-530SP, current owner has been out of the hobby for 18+ years, no antenna at sellers QTH. Will have my FT857 in my car to see if it the kenwood rig transmits and receives.

Owners stated it makes sounds when plugged in(hope to hear stations when connected to BP antenna). I am kind of hesitant to transmit not knowing what the settings for driver, plate and load parameters are after long period of inactivity. I guess the rig will have to be tuned (with owners help) or go by the manual. I would have to go slow as I am not up to speed with operating hybrid rigs.

Meanwhile , I will reading the manual and feeding my brain with info from the web.

Thx again,73, Fun Leung ,KC2TBA

Roy,

Low impedance stereo earphones work well. I've gone through about a dozen of various manufacturers picked up at garage sales or flea markets, never paying more than $1.00, until I found ones that I liked the sound. Right now I'm using Koss TD/60 but will probably keep looking.

Subject: [TS-520_820_530_830] Recommended headsets?

Hello All,

I am still a ways from getting on the air with my TS-830S. I have a nice old Shure mike for it, but I was recently thinking that, with my hearing problems, I might do better with a headset that would seal out extraneous noise and allow me to use the direct connection afforded by the voice coil switch on my hearing aids. I see that at eham there are several cheap headsets that are touted as being pretty good. Does anyone have some recommendations for a headset that would work well with the TS-830S?

TIA &73,
Roy Kersey

Hmmm Thanks Terry. Appreciate your thoughts on this, but no, we won't.
In fact, I won't be asking any more from you following this. I will sort it myself.

32050. TS 520S DRIVE CONTROL STICKY??

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-23 22:25:59 UTC
From: jeffrey l
Topic: 32050 Message: 32050

Hi all,
I am having a small issue with the DRIVE control when tuning-up,

The control seems to be sticking? I cannot get a meter reading unless I wiggle the drive control and then it is very touchy .

Would this be due to dirty contacts in the set???, and how do I correct it please.

The SET is working very well apart from this.

Many Thanks,

Jeff
VK4FNRS

32051. Re: Speech Processor alignment

The bandwidth on this thread is getting pretty wide. How about starting a new one?

32052. Re: [TS-520_820_530_830] Re: Speech Processor alignment

Thanks Mike...

Just to let you know that in the Svc Manual I have, it goes page 43 (Location of adjustments bottom view), to page 45 (which was my error, I noted it as page 44, but as it came after page 43, you'd assume... you get the picture) ;-)

So, Alas, I am missing page 44, which explains a lot.

Cheers
Chris

From: Chris Parnell
Topic: 31926 Message: 32053

OK... now I have it (Thanks to Gordon's website)

Chris

Hi Gordon,
Dunno!
I can't seem to find anywhere to check, but I expect it will be blindingly obvious after somebody points me in the right direction!
Using Windows XP and IE8.

I also see those same funny "A" and other strange characters in posts. My initial thought was the characters came from folks using cell phones to text their response, maybe because of incompatible Cell phone fonts. I can't verify this because I don't own a cell phone (don't want one either) so that's just an idea so don't take that as gospel.

I changed my options for a week to receive responses/postings through e-mail. During that period I don't recall seeing the funny "A" and other strange characters when viewing e-mail. I use Yahoo on-line e-mail. I also use Firefox 5 and have been using Firefox for quite some time, ever since Firefox 3 came out. I don't like Internet Explorer. I no longer receive responses/posts through e-mail, changed options back to web only.

32057. Re: Inspecting filters

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-24 17:40:48 UTC
From: rkersey tds.net
Topic: 32041 Message: 32057

Hi Mike,

I have looked at the operating manual. I notice that step #3 in installing the filter says remove eight screws (to remove the board) and step #7 says to replace six screws, and I guess this is a mistake. Aside from that, the manual does not specifically say that all four filters are visible on the top of the board, which is what I was asking about, but I assume that is the case and that, if they have not been harvested, all four filters will be visible once the top cover is removed. Let me know if I am wrong about that.

32058. Bandswitch: solder or silver paint TS-530S

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-24 17:25:00 UTC
From: bpierfel
Topic: 32058 Message: 32058

My TS-530S has the too common band switch issues of loose rivets. I've read some posts where people have soldered to repair it and read of others using conductive silver paint. So what do the gurus recommend? I would think that soldering would be more robust long term, but is there danger of heating the switch fingers and them loosing their springiness?

I plan to remove the RF board from the radio and remove all the wafers to perform the repair.

BTW, I'm looking for a CW filter for the 530
tnx

Roy,
When you remove the top cover and look in, this is what you should see on the TOP of the IF board if you have all four filters.
http://www.n6wk.com/kenwood/TS-830S-4%20filters.jpg
I have them numbered inside red circles

Hi Roy,

Gordon's pictures are exactly what you should see.

Yes, there are "misprints" or "typos" in the manuals. If you removed 8 mounting screws from the IF board then it stands to reason you would put 8 mounting screws back on the IF board.

Don't be fooled into believing that "GOLD" means the 830 is fully loaded with filters. You should always open the top cover and verify the presence of filters in the transceiver.

The larger filters are the 8.830Mhz first IF filter and the smaller filters are the 455Khz second IF filters.

Bob,

"Conductive paint" will not fix a mechanical connection. If the rivet is indeed loose, soldering may only last a short time as it is not designed for mechanical support. I have repaired 3 or 4 "wafer" boards with the problem you are describing with short, fine thread stainless steel screws and lockwashers/nuts, and then checked continuity of connection. Have not have a failure yet. Good luck.....

Subject: [TS-520_820_530_830] Bandswitch: solder or silver paint TS-530S

My TS-530S has the too common band switch issues of loose rivets. I've read some posts where people have soldered to repair it and read of others using conductive silver paint. So what do the gurus recommend? I would think that soldering would be more robust long term, but is there danger of heating the switch fingers and them loosing their springiness?

I plan to remove the RF board from the radio and remove all the wafers to perform the repair.

BTW, I'm looking for a CW filter for the 530
tnx

Paul:

Well, first does the set work otherwise? Does it receive and transmit and seem to be on the correct frequency according to the markings on the dial?

There are two things that can cause this problem.

1. A failure in the display unit itself, with a wee bit of corrosion on the contacts the most common problem. The corrosion does not have to be visible to cause a problem.
2. A failure in the VFO, carrier unit, or VCO/PD. This will take out the whole set, receiver and transmitter and all.

Subject: [TS-520_820_530_830] Recommended headsets?

Hello All,

I am still a ways from getting on the air with my TS-830S. I have a nice old Shure mike for it, but I was recently thinking that, with my hearing problems, I might do better with a headset that would seal out extraneous noise and allow me to use the direct connection afforded by the voice coil switch on my hearing aids. I see that at eham there are several cheap headsets that are touted as being pretty good. Does anyone have some recommendations for a headset that would work well with the TS-830S?

TIA &73,
Roy Kersey

Agreed. If the rivets are actually loose, you have to either re-rivet them (not an easy job) or use the screw remedy that Joe mentioned. Either way, you have to be careful not to crack the phenolic wafer through which the rivets go. Do that, and you're going to have to replace that entire section of the switch.

Dan,

You can, but there is a caveat. The 520 series of rigs had their VFO running from 5.5 MHz (at "0" on the sub dial) to 4.9 MHz (at "600" on the sub dial). The 820 series had their VFO running from 5.5 MHz (at "0" on the sub dial) to 5.0 MHz (at "500" on the sub dial). This will only affect you on 10M where you won't be able to cover 29.0 MHz through 29.1 MHz and 29.6 MHz through 29.7 MHz with the VFO-820 (obviously you'll still be able to with the internal VFO on the 520). Not likely to be a big issue with anyone, but bears being pointed out.

32076. TS-820 Rectifier Circuit (800V Blowing Fuse)

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-25 20:17:08 UTC
From: unnorml
Topic: 32076 Message: 32076

Have a TS-820 that worked fine when powered up last year.
Recently turned it on last week only to blow the main fuse.
Connected 100W light bulb in series with incoming power to protect transformer.
Disconnected all power from load side of transformer, reconnected back 1 at a time to find that the 800V load was causing the issue.
Disconnected 800V load from rectifier board to find problem still exists.
Disconnected ground jumper from D1, R1, D2, R2 on 800V section of rectifier board (X43-1090-02), which seemed to stop the over current draw.
So I suspected any of the Diodes and/or Resistors in this circuit.
Replaced D1 - D4 (NTE125) and R1 - R4 (470K 1/2W) on Rectifier board.
Problem still exists.
Again I disconnected the Ground Jumper from D1, R1, D2, R2 on 800V section of rectifier board. No over current draw.
Reconnected and problem arises again - repeated this twice just to make sure.
According to the schematic - this section is the only area to cause this problem.
Out of ideas and running out of hair (being pulled out)

Can something else cause the Main Fuse to blow???
Any ideas and/or suggestions would be greatly appreciated.

Mike - KI4FDH

OK - Please respond with a comment if my finding is wrong.

Checked the HV Caps and found that 1 of the caps is shorted.
No cap value and less than 2 ohms resistance.
I've ordered a HV cap replacement set from Ken K4EAA.
Hopefully this will solve my problem.

I didn't figure that these would cause this problem with the 800V disconnected from the Rectifier Board and still cause the Fuse to blow.

Any explanations would be greatly appreciated.

Mike - KI4FDH

If one or both HV filter caps are shorted, the fuse will blow.
Since you replaced the diodes and resistors on the Rectifier Unit,
I would check them to ensure they have not failed again, BEFORE, you power up the 820 after replacing the caps.

Make sure you pay attention to the polarity of the HV replacement caps. Those 2 capacitors are wired in "series". If you wire them wrong you can easily damage other circuits when powering up the 820.

Thanks for the prompt reply and the support Mike,

I don't believe I'll have a problem with the rectifier circuit, I have not given full power to it yet.
I will however, double check before power up.
I noticed the series wiring on the schematic, and will be mind full of that. I've blown electrolytics before using "reverse polarity".

I'll post a reply after the install and start up for informational and reading enjoyment.

Thank You again and 73,

Mike - KI4FDH

32080. TS-520S Low Output Power

Hey guys. Thanks for previous help, I've got another one for you.

I have a TS-520S that has low output power.
On 20m with the Mode setting on CW and keying up the output will "bump" up to around 90W and immediately drop to just less than 60W.
I have replaced the Finals and Driver tube, and performed the alignment and neutralized the finals.
Due to the age, I suspect the HV caps are getting "soft", as I have heard before.
I think they are due for replacement and was asking for any thoughts on that.

I was working on a fellow Ham's TS-820S and came across the HV caps being bad. This made me think of the output on the 520S.

Thanks for any and all words of wisdom.

Nike,

Check the voltage on the HV caps with a VOM/DMM..capable of 1,000VDC....the panel meter may not be accurate due to aging resistors in that circuit, but may give you a clue as to how much the voltage is "sagging." At "idle" it should be 900+ volts...you can measure again with the "heater" on. Then "tune-up" for max output...and measure voltage again while key down...BE CAREFUL...you are messing around volts that can make you SK. You should see about 780+ or so volts on KEY DOWN...less than about 750V key down usually indicates bad cap or caps. Replacement kits are readily available. But measure the resistance of the screen and cathode resistors on the final board. They are readily visible with the bottom removed. If these are out of value or get out of value when "stressed" .... ie.. get hot from lots of volts going through them you may also have loss of power indication. If you have high Ip(plate current) low output...say 60-70 or so watts and
good high voltage...look at the cathode resistors before you just go replacing tubes..etc. Are you measuring the output with the panel meter or outboard watt meter? Is this the only band in which this happens?? Did the rig have the same problem(s) with the old finals and driver?? You can get a good look at the resistors you need to "meter out" by looking at K4EAA's web site...lots of good info and pictures. Nice thing about the 520(s)...you don't have to remove the final board to replace any of the screen or cathode R's!

Nike,

You did not provide the HV and IP current level indications at both 90 watts and 60 watts.

While it's possible the HV filter capacitors could be causing your problem, without knowing what the voltage and current levels (HV and IP), it's difficult to determine where the problem could be.

If you would, please, tune the 520 up to full power then note the HV and IP current levels at 90 and 60 watts.

Lets look at an example that could be causing your problem "if" one of the HV filter capacitors is bad. The voltage and current levels may not be exactly what your 520 is indicating. I use them only as an example.

For example, lets assume the HV sags from 850VDC in standby to 450VDC in CW transmit. Lets further assume the IP indication is 125ma. With these 2 HV and IP current indications, the power input in the final amplifier will be

.125 x 450 = 56.25 watts

Since the typical efficiency of the final amplifier is 55%, the power output would be

56.25 = 45% = 30.9 watts

Again, this example is just that, an example. Without knowing what your 520's HV and IP indications are at 90 and 60 watts output, it's difficult to say what is actually causing your problem.

When measuring the final amplifier's HV at full output, measure the HV at the "Rectifier Unit's 800" terminal, NOT at the final tube plate caps. RF at the final tube plate caps will contaminate the DC voltage resulting in an invalid DC voltage indication.

Mike,

Typically, if one or both of the HV filter capacitors short internally, they take out one or more of the HV rectifier diodes as well.

Once you have replaced both HV filter capacitors, notice I said "both", check the four HV rectifier diodes, D1 thru D4, to be absolutely sure they are okay. Assuming diodes D1 thru D4 are okay, especially when the HV filter capacitors have shorted internally, can easily result in no HV to the final amplifier tubes. Never assume or guess anything, always check the component(s) to be absolutely sure. Just because a diode's body does not show any signs of overheating, crack bodies, etc, does not mean they are okay. That is why I said check the diodes to be sure. If one of the diodes is open, replace the all. Diodes are cheap and you don't know the condition of the other 3 diodes. You can use 1N4007 1KV 1amp diodes to replace the original diodes D1 thru D4. Just be sure you ensure the diode's banded leads are inserted into the correct holes in the board.

Topic: 32085 Message: 32085

I'll try this again as I got no response on my first post...

I have a fellow Ham in Australia that wants the following boards:
Ant Coil bd..... X44-1070-00 (I have a X44-1170-00)
Mixer Coil bd..... X44-1080-00 (I have a X44-1180-00)
Drive Coil bd..... X44-1090-00 (I have a X44-1190-00)

My 520S serial is 651215
I wander if he may have an earlier 520S & Kenwood came out with the ones I have...

Are the above boards the same?_____
Thanks in advance.
Bob

Agreed, and if you fire up the rig with a shorted rectifier you will almost certainly ruin the new caps you have just fitted.

Can't stress this enough; double check that all the diodes are OK and showing the correct forward voltage of 0.5ish to 0.7ish volts, and infinity (or many megohms) in reverse.

Unsolder one end of each diode to test it - don't test in circuit.

Good luck, I hope you get to the bottom of this.

32087. TS-520, TS-529S, and TS-520SE...differences?

Topic: 32087 Message: 32088

The 520 series transceivers were "basically" the same.

TS-520
Power rating:
120/240 VAC = SSB 200 watts PEP and 160 watts DC input
13.6VDC at 20 amp - 120 watts PEP and CW 90 watts DC input

Bands covered:
80 thru 10, no 160 meters and no WARC bands

DC to DC converter was standard from the factory

Remote VFO-520 or VFO-820 will work, plug and play, no mods required

No receive RF ATTN push button

Meter switch is an outer ring switch with the PLATE control

4 position FIXed crystal select switch right of meter

JJY/WWV band is selected with a push button on lower left of the VFO

No DG-5 digital HET, CAR, VFO, and 13.6VDC connections on rear panel

No Phone Patch IN/Out connections on rear panel

CW/SSB filter select through Mode switch. No Narrow/Wide filter select switch.

TS-520S
Power rating:
120/240VAC = SSB 200 watts PEP and CW - 160 watts DC input
13.6VDC (optional DC to DC converter required for battery power) SSB 120 watts PEP and CW 90 watts DC input

DC to DC converter is "optional", no longer factory standard

Bands covered:
160 thru 10, no WARC bands

JJY/WWV is made part of the band switch

4 position FIXed crystal select is moved as an outer ring switch on the PLATE control

Meter switch is moved to the right of the meter

Receive RF ATTN "push button" replaces the JJY/WWV band push button on the lower left of the VFO

HET, VFO, CAR and 13.6VDC connections on rear panel for connection to DG-5 digital display

Added Phone Patch IN/OUT sockets on rear panel

Remote VFO-520 or VFO-820 plug and play. No mods required

CW/SSB filter selection through Mode switch. No Narrow/Wide filter select switch.

TS-520SE
Power rating:
120/240VAC SSB 200 watts PEP and CW 160 watts DC input

No DC operation option, primary AC power (120/240VAC) operation ONLY

Same HET, VFO, CAR and 13.6VDC connections on rear panel for DG-5 digital display

CW "Wide/Narrow" filter select switch replaces "Heater" switch. Filaments are wired directly to the 12.6VAC secondary winding. No way to turn filament OFF.

VFO-520 and VFO-820 work "Plug and Play". No mods required.

No "X-Verter" 6 and 2 meter option.

There are circuit improvement changes made but the lists above are the most obvious differences between the 3 different TS-520 models.

Hi Bob,

Yes there are differences in the boards in the TS-520 series.

The boards requested by the Australian ham appear to be from his "TS-520" transceiver. The TS-520 was the first transceiver in the series of 520 transceivers.

The board numbers needed by the Australian ham appear to be incorrect.

The Ant Coil board is not X44-1070 but rather X44-1090-00

The Mixer Coil board is not X44-1080-00 but rather X40-0018-01

The Driver Coil board is not X44-10900-00 but rather X40-0017-01

The boards you have are from either a TS-520S or TS-520SE. They will not work, plug and play, in a TS-520.

You should ask him for the PC board "Foil side" number on the boards he is needing. Simply turn the boards over and look at the foil side. There is a number visable on the foil side of the board. The only way to ensure he is getting the correct boards for his transceiver is for him to tell you the exact model (TS-520, TS-520S, or TS-520SE) and the foil side number on each board he needs.

I hope this helps.

Topic: 32085 Message: 32090

Bob,

The Antenna, Mixer, and Driver boards are small individual boards on the bottom of the 520 mounted between a metal bracket. The band switch shaft runs through all of these boards. These boards are not incorporated in the RF Unit board like they are in the TS-820/820S.

It appears he has not given you the correct component side "X" number for the board's he needs. He should look on pages 48 and 49 of the TS-520 operator's manual, the pictures show what each board's "X" number is and what the board is, i.e., Driver, Mixer, and Ant Coil Unit boards.

As I stated in my last response, he need to provide you with not only the component side "X" number but also the foil side number for each individual board he needs. For example, he needs to do the following

Ant Coil Unit
X44-1090-00 / <Foil side number>

Mixer Coil Unit
X40-0018-01 / <Foil side number>

Driver Coil Unit
X40-0017-01 / <Foil side number>

This will ensure you are giving him the correct boards that will work in his 520.

The 520 series transceivers were "basically" the same.

TS-520

Power rating:

120/240 VAC = SSB 200 watts PEP and 160 watts DC input

13.6VDC at 20 amp - 120 watts PEP and CW 90 watts DC input

Bands covered:

80 thru 10, no 160 meters and no WARC bands

DC to DC converter was standard from the factory

Remote VFO-520 or VFO-820 will work, plug and play, no mods required

No receive RF ATTN push button

Meter switch is an outer ring switch with the PLATE control

4 position FIXed crystal select switch right of meter

JJY/WWV band is selected with a push button on lower left of the VFO

No DG-5 digital HET, CAR, VFO, and 13.6VDC connections on rear panel

No Phone Patch IN/Out connections on rear panel

CW/SSB filter select through Mode switch. No Narrow/Wide filter select switch.

TS-520S

Power rating:

120/240VAC = SSB 200 watts PEP and CW - 160 watts DC input

13.6VDC (optional DC to DC converter required for battery power) SSB 120 watts PEP and CW 90 watts DC input

DC to DC converter is "optional", no longer factory standard

Bands covered:

160 thru 10, no WARC bands

JJY/WWV is made part of the band switch

4 position FIXed crystal select is moved as an outer ring switch on the PLATE control

Meter switch is moved to the right of the meter

Receive RF ATTN "push button" replaces the JJY/WWV band push button on the lower left of the VFO

HET, VFO, CAR and 13.6VDC connections on rear panel for connection to DG-5 digital display

Added Phone Patch IN/OUT sockets on rear panel

Remote VFO-520 or VFO-820 plug and play. No mods required

CW/SSB filter selection through Mode switch. No Narrow/Wide filter select switch.

TS-520SE

Power rating:

120/240VAC SSB 200 watts PEP and CW 160 watts DC input

No DC operation option, primary AC power (120/240VAC) operation ONLY

Same HET, VFO, CAR and 13.6VDC connections on rear panel for DG-5 digital display

CW "Wide/Narrow" filter select switch replaces "Heater" switch. Filaments are wired directly to the 12.6VAC secondary winding. No way to turn filament OFF.

VFO-520 and VFO-820 work "Plug and Play". No mods required.

No "X-Verter" 6 and 2 meter option.

There are circuit improvement changes made but the lists above are the most obvious differences between the 3 different TS-520 models.

32095. Basic troubleshooting question - How do I trace a signal?

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-28 01:37:43 UTC
From: b.mcmillan@sbcglobal.net
Topic: 32095 Message: 32095

Greetings to all,

I recently upgraded to General class and have purchased two Kenwood radios to set up my first HF staion. Both radios have transmit issues and since this group seems to have some very talented minds I thought I would ask a general question.

Here is my issue on each radio;

TS430 - recieves fine,but on transmit the ALC meter pegs out and there is no output.

TS520s (I love this radio!)- recieves fine and seems to transmit OK in CW but very low power in SSB(maybe 10 watts).

I'm afraid I know enough to be dangerous but not enough to isolate the problems.

I have the service manuals but I don't know how to trace the signals. Can anyone tell me the proper procedure for tracing a signal from the mic to the antenna? Also, the schematic shows voltage readings at various points. How exactly do you test these volatges.

I have really enjoyed this group for the past several weeks and I am learning a lot!

Thanks for any guidance. Also,if there is a good book on this subject please let me know as I am very good at learning this way.

73,
Bill
N0YUD

32096. TS-830S Sudden loss of output power

Topic: 32096 Message: 32096

Hi folks,

Today I've been doing some adjustments to my TS-830S, fixing a broken PROCESSOR switch, and replacing the 12BY7A driver because the previous one started showing wear (half power output, no ALC action).

I successfully replaced the 12BY7A, and could get full output power and ALC deflect.
So I adjusted BIAS potentiometer to read 60mA in the Ip scale.
So far so good, until I tried to transmit again, and my wattmeter only showed 2 watts !!!

I have excellent TX audio as I checked it with another rig, but I have no way to increase the power.
I tried installing the old 12BY7A but no change here, also very low output.
I can see the glow of both 6146's, but I don't know what to do.

Please help me, and thank you in advance.

The drive control is very stiff and the reactive range for the control appears small??

On 80Mt I find that I have trouble getting a reading on the meter with out moving the control through it's range a couple of times.

What is the cause of this ? and how do I fix it..

Hi Jeff,

A stiff DRIVE control could be caused by dirt collection in the DRIVE control hardware and bearings in the variable capacitors. A good cleaning of the hardware, shafts, and capacitor bearings would help.

Hello Guillermo,

Measure the voltage on the driver tube first.

Connect the DC volt meter's RED lead to pin 2 of the driver tube socket and the Black lead to the 830s chassis.

The voltage in receive should be approximately -43VDC.

The voltage in transmit should be approximately +.4VDC

If the voltage does not change, remains "negative" then I suspect the problem is caused by the relay on the AF Unit board.

Hello Bill,

You asked for reading material. I recommend reading the operator and service manual's "Circuit Description" section. This will help you understand how the 520 stages work and each stage contributes to the overall operation of the 520.

I also recommend studying the block diagrams in the operator and service manuals. This will show you how the signal flows in both transmit and receive.

I can give you a more detailed description of how the signals flow, including how the mixing circuits produce the "desired" signal if you drop me an e-mail. I'm good on here but my e-mail address is w5rkl at yahoo.com

I'm not familiar with the TS-430 so I can't comment on it. I can only suggest doing the same, read the circuit description section in the 430 manuals.

Hi John,

The VFO does not operate at 1.5Mhz or any of the other band switch setting frequencies. The VFO frequency range is between 5.500Mhz and 6Mhz on ALL bands. The VFO, Carrier signal, and VCO oscillators in the PLL Unit produce the correct frequency that is applied to the RF Unit in both transmit and receive. If you have the operator and/or service manual for the 530, I recommend reading the Circuit Description so you have a better idea of how the overall operation in the 530 occurs.

32105. Parts Only TS-830S RF Board

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)

Topic: 32105 Message: 32105

I am working on Joe Loverti WW8X TS-830S RF Board. I need 2 small green case radial lead ferrite core RF inductors/chokes.

L1 is 2.7uhy and L42 is 470uhy. (actually replacing L36 in driver plate supply but prefer a 470uhy choke that has not seen plate current so selected L42 to harvest)

I have checked with Mouser and Digi-Key and they do not stock these chokes.

Anyone have a parts only RF board that they would be willing to pull these from or just sell the board to me? Board can be in bad shape and have bad foils, jumpers, etc. Does not have to have the drive variable capacitors etc.

Thanks-Terry K9TW

32107. Which oscilloscope?

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-28 09:26:07 UTC
From: Sander Wissing
Topic: 32107 Message: 32107

Hi everyone,

I need to work on my TS830s, and while I suppose I can muddle along
for a while without an oscilloscope, now is probably a good time to
invest in one.

The options are:

20MHz analogue. (I assume a 'normal' oscilloscope is analogue?
40MHz analogue
60MHz analogue

and then the USB connected digital storage scopes like the Velleman
PCSU1000 which seems to be able to sample up to 60MHz.

Price wise the USB scope slots in between the 20MHz and the 40MHz scopes.

So the questions are:

1. I have always assumed the analogue scopes are better than the
digital storage scopes. Is this true?
2. If I have to stick to the analogue scopes, is a 20MHz unit OK
for radio work? Or will I always regret not buying the 40MHz unit?
The 60MHz unit is fairly expensive, so if the 40MHz unit is not good
enough I will need to postpone the purchase a month or so.

Sorry for the Off Topic! :)

Thanks!

Thanks Mike, in a few hours I will check everything that my knowledge allows.

It's amazing because the needle meter shows as if everything is fine (I get ALC movement, 60mA Ip at SSB with no input, about 760 HV, full deflection when the S-meter switch is in RF).

Very strange.

I will update this post later when I finish the tests.

Thanks everyone,
Guillermo.

You said the HV is "760VDC". I assume that is the HV after tuning the transmitter for full output. Is that true??

Also, what is the meter showing as the IP (Meter switch set to IP) at full output (760VDC)?

If the IP current is 220ma with HV at 760VDC yet you only see approximately 10 watts output then I would look at the antenna change over relay located at the bottom of the final unit PC board, the relay terminals may be carbon coated. You said the meter switch set to RF indicates full scale which tells me either the RF pot on the rear panel is set wrong or the RF pot is set properly and the final amplifier through the PI Network is producing full output but that RF output is not appearing at the rear panel's SO-239 antenna connector. The RF goes through the T/R relay but the RF pot is "before" the T/R relay.

If the T/R relay is causing your low RF output, I believe the tuning of the PLATE and LOAD controls would not be "normal". The IP dip and LOAD peak RF output adjustments would not results in normal indications because the output of the PI Network is not seeing an impedance load that is within the range of the PI Network (50 to 75 ohms).

Hi Sander,

If you have never used an oscilloscope before then I recommend a simple analog oscilloscope until you get familiar with and learn how to use an oscilloscope.

What ever scope you buy, makes sure the probe(s) come with it. If it's a dual trace scope you will need 2 probes. If the scope does not come with probes you will need a basic set of 1X/10X probes.

An inexpensive analog scope, doesn't have to be dual trace, will allow you to learn how to use it. There are many places on the Internet where you learn "free" by simply going to and reading the "How to" on use of an oscilloscope. For most basic amateur radio scope requirements, a 20Mhz scope will do fine. Yes, a 60Mhz scope will be much better. There are quite a few on eBay under Consumer Electronics. Simple enter "Oscilloscope" in the search and you will see the various oscilloscopes for sale.

Here's an example of a simple "BRAND NEW" oscilloscope on eBay. It comes with a probe

http://cgi.ebay.com/MCP-CQ5010C-COMPACT-10MHz-COMPACT-OSCILLOSCOPE-PROBE-/200580351390?pt=BI_Oscilloscopes&hash=item2eb385459e

This is a simple scope to learn on plus it's brand new with the probe.

Sander--There are some really good O-scope tutorials on You Tube. I believe the best are made by W2AEW. If money is not object I would get the 40 mhz as some of the cheaper 20mhz dont do a good job at 28mhz where you would need it to use as null detector for final tube neutralization. I used Heath single and dual trace scopes for years before finally getting kids out of the house and upgrading to Tektronics 100 mhz dual trace. These are good for sweeping filters, but to be honest I dont use it as much as I do my RF millivolt meter and RF signal generator and of course good high Z multimeter. If I was prioritizing scope wouldnt be first piece of test equipment to buy. Just my 1.5 cents worth!--Terry K9TW

Topic: 32105 Message: 32115

Gordon--Thanks I will keep your offer in mind. I offer the following to all who may experience a shot of RF into the receive path.

I measured Joes rewound L41 and it just about spot on to the baseline ohms and inductance readings you gave us. I reinstalled L41 in the board . I injected 10 mv 1.9Mhz signal at TP-1 (because he sent it to me in the 1.5 Mhz position) and measured output at VC-1 and got something less than 10mv. Went back to C1 1800pf (mylar film) coupling cap and pulled it and found it to read approx 1400 pf which surprised me due to normal close tolerance on this kind of cap. Not enough to account for signal loss. I then pulled L1 2.7uhy choke in the broadcast band high pass filter and measured it. I have no other specs other than 2.7uhy and I get very weird low ohms and inductance readings. I also noticed that the top half of L1 is very discolored dark brown/black around entire top (as if overheated). Couldnt really see this very well in circuit. As you know these chokes are all bright green cans.

I had a 6.8uhy choke in one of Ken K4EAA final repair kits and stuck it in place of L1. Reinjected 10 mv 1.9mhz at TP-1 and now get approx 75mv output at VC-1 that I can peak with the driver cap shaft and by tuning L41 slug. I now know L41 is working as it should. So looks like the Xmit RF took out L41 xfmr and the L1 choke. L1 apparently has shorted turns and is shunting nearly all the rf to ground. Not sure if you have seen this before or not?

I cant leave the 6.8uhy choke in the circuit as it changes the cutoff frequency of the high pass filter. If you havent seen it there is really great free filter design and analysis software tool on AADE website. He sells a nice digital LC meter kit. It is fun to plug in differing values for C and L in the high pass filter circuit and see the effect on the cutoff frequency. I have downloaded the software on to my laptop.

So long story but looks like L1 was problem in addition to L41 and something to look at with any future burned up L41 transformers. Bad L1 probably talked Joe into a 2nd rewind of L41? I did pull L2 4.7uhy choke (2nd dipole of high pass filter) and it read dead on 4.7uhy on my bridge and showed no signs of discoloration.

I will get back to you if I cant find a 2.7 uhy L1 replacement. Thanks Terry K9TW

Thanks Mike,

One of the drawbacks of living in South Africa is that we are far enough from the rest of the world to make ebay bargains expensive in postage. And the same goes for buying from US distributors. But your advice is taken! I will look for a cheapish used oscilloscope, but if I can't find one anytime soon I will be comfortable with a 20 MHz unit which aren't that expensive either...

Thanks,
Sander, ZS6SSW

Howzit Sander,
I bought my 'scope for R10 when I lived in SA in 2000.
An old Phillips PM3200 valve model 10 MHz.
Try a local rally and talk to your local radio club.

32120. TS830s no receive, low output

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-28 19:29:14 UTC
From: Sander Wissing
Topic: 32120 Message: 32120

Hi everyone,

I recently acquired a TS830s with problems. This radio stood for a year or so and was then discovered to have no receive and reportedly only about 30w output. The radio was then left for another year and then changed hands for a good price. It may have been struck by lightning.

I have replaced the finals with a supposedly good set, and confirmed that there is no receive. I get whitenoise and the AF gain works. Also filters etc. makes a difference to the noise. And there is a surprising number of birdies present when tuning around. I was feeding a 50uV signal into the antenna connector and not a peep, but I do get pops when I connect or disconnect something to the antenna connector. I have not even tried to get anything done on transmit. Based on a recent post about Q1 affecting receive and transmit I started there. What is the pinout of Q1?

Looking down from the front panel, I have labeled the legs as follows:

1 2
\ /
O
/\
3 4

In receive I get these voltages:
1 4.01v (slowly stabilizes as if the multimeter is charging up a cap or something)
2 11.76v
3 1.146v
4 0.936
The shell of Q1 is at 1.146v as well.

This is significantly different from the schematic, the question is, does anyone have a hunch why? I will trace the schematic further and see if I can figure it out, but any leads are welcome!

I also tried to set the bias, but with the meter in IP, the needle never moves, regardless of bias pot setting. This may or may not be related, but it may also be an error in my technique... If anyone feels like talking me through a bias adjustment real slowly I would appreciate it.

Thanks,
Sander, ZS6SSW

Hi Sander,
I'm new to the hobby (two years next month) and am learning to maintain my Kenwood radios. My most recent project was replacing a corroded back panel on my 830s with a nice one from Bob Mansker. Upon reassembly, the radio powered up but nothing else. After searching the files of this group I looked at the microswitch attached to the remote vfo socket and found it to be malfunctioning. After some tinkering it is now working properly as is the radio. The microswitch serves the same purpose as the vfo jumpers used on the 520 and 820 series. It may be totally unrelated, but is worth looking at.

Sander-- Here is quick test. Touch you antenna center conductor or your finger to VC-1 at the 2nd or back solder lug terminal (the first air variable cap on right side of the RF board). This will input a signal to G1 of Q1 dual gate mosfet RF amp. You should see very noticeable gain in noise and/or actually copy signals. Make sure RF gain control is at full CW max position.

Your Q1 voltages are good accept for Pin 1 which is Gate 2 and should read approx 2.7 volts in receive with RF gain at max. AGC applied to G2 controls gain by determining how hard you turn Q1 on. Pin 2 is the Drain and should read approx 12.4 vdc, Pin 4 is the Source and should read approx 1.0 vdc, and Pin 3 is Gate 1 and should read approx 1.1 vdc.

You need to use a high impedance meter to make these readings like an old Heath 11Meg input VTVM. Many newer DMMs have around 2 meg input impedance especially on the lower ranges and will affect your readings.

So only reading that looks odd to me is at your Pin 1 or G1. Should be approx 1.1 in receive and -2.9 in xmit. You can think of G1 as equivalent to the control grid on a tube amp. I dont think there is anything wrong with Q1 (not shorted or not open) based on readings you obtained. Terry K9TW

Subject: [TS-520_820_530_830] TS830s no receive, low output

Hi everyone,

I recently acquired a TS830s with problems. This radio stood for a
year or so and was then discovered to have no receive and reportedly
only about 30w output. The radio was then left for another year and
then changed hands for a good price. It may have been struck by
lightning.

I have replaced the finals with a supposedly good set, and confirmed
that there is no receive. I get whitenoise and the AF gain works.
Also filters etc. makes a difference to the noise. And there is a
surprising number of birdies present when tuning around. I was
feeding a 50uV signal into the antenna connector and not a peep, but I
do get pops when I connect or disconnect something to the antenna
connector. I have not even tried to get anything done on transmit.
Based on a recent post about Q1 affecting receive and transmit I
started there. What is the pinout of Q1?

Looking down from the front panel, I have labeled the legs as follows:

1 2
\ /
O
/\
3 4

In receive I get these voltages:
1 4.01v (slowly stabilizes as if the multimeter is charging up a
cap or something)
2 11.76v
3 1.146v
4 0.936
The shell of Q1 is at 1.146v as well.

This is significantly different from the schematic, the question is,
does anyone have a hunch why? I will trace the schematic further and
see if I can figure it out, but any leads are welcome!

I also tried to set the bias, but with the meter in IP, the needle
never moves, regardless of bias pot setting. This may or may not be
related, but it may also be an error in my technique... If anyone
feels like talking me through a bias adjustment real slowly I would
appreciate it.

Thanks,
Sander, ZS6SSW

Sander,
If you have never used or owned a scope before start with a plain analog scope, even a tube type (valve type). I would stay away from many modern used digital scopes due to the custom I.C.s that are used. If they fail replacements may not be available.

Start with a 100 MHz if it fits your budget. The higher the bandwidth the better.
Single channel is fine for 90% of what you will probably do.
Dual Trace, Dual Beam and such only add to complexity and cost. Not needed if you are a beginner oscilloscope user.

As far as brands. It depends what is available as good used equipment near your location. Here in the States I would sarcastically say "is there anything other than Tektronix?" simply because they are the best (IMHO) others may disagree. HP are fine. Their older scope trigger a bit slower than the Tek do and their solid state are filled with specialized I.C.s and if you get a scope with a failed input amplifier I.C. for instance they are not available unless another socpe is purchased for parts. HP makes excellent and very comparable scopes to Tek. Philips also makes some very nice scopes. I am not familiar with most of them though.

Check out the scope before you buy it and ensure all the functions work and you can get a nice clean trace that is even thickness from one end of the screen to the other.

A few ideas that I hope can head you in the direction you want to go.

73,

Bill

Hi everyone,

I need to work on my TS830s, and while I suppose I can muddle along

for a while without an oscilloscope, now is probably a good time to

invest in one.

The options are:

20MHz analogue. (I assume a 'normal' oscilloscope is analogue?

40MHz analogue

60MHz analogue

and then the USB connected digital storage scopes like the Velleman

PCSU1000 which seems to be able to sample up to 60MHz.

Price wise the USB scope slots in between the 20MHz and the 40MHz scopes.

So the questions are:

1. I have always assumed the analogue scopes are better than the

digital storage scopes. Is this true?

2. If I have to stick to the analogue scopes, is a 20MHz unit OK

for radio work? Or will I always regret not buying the 40MHz unit?

The 60MHz unit is fairly expensive, so if the 40MHz unit is not good

enough I will need to postpone the purchase a month or so.

Sorry for the Off Topic! :)

Thanks!

Hi Mike, I just came back from working with the 830 at the house of my friend, who is the owner.

The first thing I did is measure voltage at pin 2 of the drive socket, as you advised me. The voltages were as you said, so nothing wrong there.

Before putting the newest 12by7a, I sprayed some contact cleaner and pushed down the socket.
After installing the new driver, voila! Full power output again.

After that, I measured at idle:
Ip: 60 mA.
HV: 800 V.

At full output in CW mode, the meter shows:
ALC: top of the ALC range.
Ip: about 240mA.
HV: 750 V.

It appears as everything is working fine. I left the unit open so I can go on testing it tomorrow and check how it behaves.

Thanks Mike for your time and answers.
Guillermo.

Hi Guillermo,

With 750VDC on the plates of the final amplifier and 245ma of plate current in CW mode, that's equal to 180 watts DC input. That's the correct CW DC input power rating for the TS-830.

If your watt meter is an "average" watt meter, the most power output you will see with the 830 MIC gain adjusted so the ALC meter indication just barely starts to flicker above zero, the most you will see on an average watt meter is between 20 and 30 watts on voice peaks. If that's what you are seeing then there is nothing wrong with the 830 transmitter.

From: Sander Wissing
Topic: 32120 Message: 32129

Hi Terry,

Yes, I was talking about Q1 on the RF board. And yes, I made a noob mistake in asuming that there is only one Q1... So my Q1 isn't whichever one was involved in receive and transmit. Mine is a metal case and the voltage on G2 varies between 1.7v with RF Gain at min to 7.3v with RF Gain at max. The book says the meter has a 10MOhm impedance, but the voltage at G2 is still being pulled low by the meter.

Injecting a signal at the solder lug on VC1 makes no difference whatsoever and neither does injecting it directly on G1 of Q1.

Next step is to inject a signal at TP4 to eliminate the next step up transformer on the way to Q2. Injecting a signal on TP4 I get a very distinct increase in audio from the speaker. So this really points to the transformer between Q1 and TP4, doesn't it? On the level diagram this transformer doesn't have a name, so I will go through the schematic and see if I can identify it.

So now I have three clues:

1. No audio if I inject on Q1, but audio if I inject on TP4 (RF board)
2. Too high voltage on G1 of Q1 (RF Board)
3. No IP indication when trying to set bias.

Thanks!

Sander--I will measure my AGC voltages at G2 and report back to you. Appears you are following proper troubleshooting process.

With increase in receiver noise with signal at TP-4 it appears that Q2 buffer amp and the RIF mixer is working. I believe you are referring to Xfmr L13. I have never heard of it failing. More commonly L41 antenna step-up xfmr is the culprit.

Ken K4EAA reports on his site that he has found diode D2 shorted which would shunt G1 signal to ground. I dont think you can get meter probes on D2 in circuit to test it and it is shunted by couple of resistors.

If you were able to measure the Drain voltage of Q1 can you inject signal there? That would prove L13 good if you get increase in noise. When in injecting signal make sure you use a frequency that is same as your bandswitch position and peak the driver control while injecting. Terry

Subject: Re: [TS-520_820_530_830] TS830s no receive, low output

Hi Terry,

Yes, I was talking about Q1 on the RF board. And yes, I made a noob mistake in asuming that there is only one Q1... So my Q1 isn't whichever one was involved in receive and transmit. Mine is a metal case and the voltage on G2 varies between 1.7v with RF Gain at min to 7.3v with RF Gain at max. The book says the meter has a 10MOhm impedance, but the voltage at G2 is still being pulled low by the meter.

Injecting a signal at the solder lug on VC1 makes no difference whatsoever and neither does injecting it directly on G1 of Q1.

Next step is to inject a signal at TP4 to eliminate the next step up transformer on the way to Q2. Injecting a signal on TP4 I get a very distinct increase in audio from the speaker. So this really points to the transformer between Q1 and TP4, doesn't it? On the level diagram this transformer doesn't have a name, so I will go through the schematic and see if I can identify it.

So now I have three clues:

1. No audio if I inject on Q1, but audio if I inject on TP4 (RF board)
2. Too high voltage on G1 of Q1 (RF Board)
3. No IP indication when trying to set bias.

Thanks!

Sander--Measured my G2 (AGC) at Conn 5 Pin 1 as follows:
With no signal get approx 2.9 volts RF gain max and approx. 0.70 RF gain minimum. With Marker on and peaked and AGC on SSB get approx 2.0 with RF gain at minimum.

Suggest you measure RF1 at Audio Board Connector 9 Pin #5. Should be 3.6 volts and is adjusted with trim pot VR-3. Need bottom cover of rig off and turned on its side to access this point.

I am not ignoring inability to set tube bias. Just focusing on receive problem. Terry

Terry - thanks for the compliment! I hope my scope videos are helpful to people. For those that haven't found them, my videos are on my YouTube channel:
http://www.youtube.com/w2aew

In addition to those videos, I helped to teach a comprehensive Oscilloscopes Basics class for the NJ Antique Radio Club. This 2hr class was recorded and also put online. You can find this video linked as a "Favorite" from my YouTube page. I've also included the link for this video below:
http://www.youtube.com/watch?v=8ZKMrzTGxLQ
Since this is a long video, please see the Comments section below the video for a timeline, or table of contents that you can use to fast forward or rewind to review specific portions of the class.

I hope you all enjoy!

Alan:

Thanks for the link to your videos. I have 5 Oscopes and I really should learn how to use one!

I bought my first OScope at a hamfest for $1.00, a WWII vintage TS-34/AP radar test set. I found the tubes were Okay but all of the 2W carbon resistors had opened up. Replacing them enabled me to focus the trace, but I don't know what it really is good for.

I got a big rack mount Tek scope for free from friend when he replaced it with a later model; I have never used it. When he passed away I bought the later one, a 100 MHZ Tek scope with a built-in Freq counter, from his widow. I don't think I could have fixed my TS-820S without it, and using it was a ball, even if it was occasionally puzzling when I flipped the wrong switch.

I got a Tek 467 portable model for $35 including shipping on ebay. I had to hook up a power cord for it and it works. But I found the 100 MHZ Tek to be much better for the work on the Kenwood, since I had to go higher than 20M and the freq counter was very useful as well as superior to the stand alone counter I have at HF freqs. I definitely recommend a scope with a built in freq counter, since the signal you are measuring may not be strong enough to drive both a counter and a scope.

I bought a Nonlinear Systems Miniscope and NLS DVOM at a local fleamarket for $5.00. I fixed the Miniscope and got it working, including putting in new batteries. It is way cool but frankly the screen is so small I doubt it is very useful.

So I need to sit down with one of these instruments and watch your videos.

Thanks!

Robert

The TS-34 is not really good for much. The other scope we had was the
USM-24. Both were really only usable for audio work. And neither have
triggered sweep.

Sounds like a good scope collection! Learning how to get the most out of the scope will certainly pay dividends down the road with your repair, alignment and monitoring tasks...

Topic: 32114 Message: 32139

I bought my 520 from a local ham radio store just after the 520-S was released, I bought the new rig, the VFO-520 and a 3 element HyGain 10M Yagi all for $ 600 and change.

I am guessing it was in 1974 but need to dig out the receipts from the archives.

Subject: [TS-520_820_530_830] A few 520 history questions....

I was just wondering if the 520 was phased out when the 520s hit the market? What was the years the 520 was maufactored with the brass fan cage? What was the price of the 520 and 520s?

Thank you, Brian NC KB4MNG

Hi Terry,

I don't know about good troubleshooting process, just trying to keep some common sense... Yes, I have also come up with L13 Xfmr, but it is a big heavy part and no obvious way to inject a signal anywhere there. G1 (on Q1) isn't at ground potential, so I suppose that means D2 isn't shorted. OK, checked again and even with D2 shorted it still isn't a DC path to ground, so disregard that.

D2 measures forward voltage of about .4v, but I am not sure if this means anything in circuit.

Injecting a signal on drain of Q1 doesn't seem to make a difference. I am injecting a signal at 14.175, with the radio set to 14.175 as well, purely because that is where the schematic says to measure voltages. What is weird though, is that injecting the same signal on T4 is softer than injecting it on T2. As I understood the level diagram a signal on T2 would sound softer, or alternatively you would need to inject more signal to have the same output. Also when I pick up more noise when injecting on TP2 / TP4, turning Drive doesn't make any difference, so I am not sure what you mean by peaking drive. Also, you said 'with marker on' , what is the marker?

Measuring AGC on Conn 5 pin 1 I get 1.8v (RF Gain min) to 8.3v (RF Gain max).

On Af board, conn 9, pin 5 (RFI) measures at 8.79v, but I can adjust it to 3.6 with VR3. Should i just adjust it or is this indicative of a problem somewhere else? After adjusting VR3 to have RFI at 3.6v, AGC on Conn 5, pin 1 on RF board now measures 0.9v - 3.3v

And lastly, I didn't mean to be pedantic about the bias, just keeping tally of all the issues, still hoping someone will look at the list and say, "o yeah, all of those will be caused by x' and save us all a lot of trouble shooting! :)

Thanks!
Sander

Sander--I will measure my AGC voltages at G2 and report back to you. Appears you are following proper troubleshooting process.

With increase in receiver noise with signal at TP-4 it appears that Q2 buffer amp and the RIF mixer is working. I believe you are referring to Xfmr L13. I have never heard of it failing. More commonly L41 antenna step-up xfmr is the culprit.

Ken K4EAA reports on his site that he has found diode D2 shorted which would shunt G1 signal to ground. I dont think you can get meter probes on D2 in circuit to test it and it is shunted by couple of resistors.

If you were able to measure the Drain voltage of Q1 can you inject signal there? That would prove L13 good if you get increase in noise. When in injecting signal make sure you use a frequency that is same as your bandswitch position and peak the driver control while injecting. Terry

Topic: 32120 Message: 32141

Sander--I will try to respond to each point
1. I believe D2 is the agc delay diode. It is a very fast switcher and Ken K4EAA noted hybrid expert reports finding it shorted. D2 ensures that the agc is held off or delayed during static crashes, ignition noise spike etc. Just wanted to make sure D2 was not shorted and shunting G1 signal to ground thru cap C44.
2. Injecting signal at Drain of Q1 and getting good signal out was to prove that transformer L13 was not bad.
3. If you inject 14.175 mhz with bandswitch in the 14 mhz position you should be able to vary the Driver control either side of normal 1200 position and get a peak. Just wanted to make sure you had receive path optimized for weak test signal. It is important that you use as low a test signal as possible especially if you are using one of the older Heath/Knight/Eico signal generators that are not shielded and do not have calibrated attenuator. You dont want the signal to swamp the front end. I would think 10 mv would be more than adequate. If you have better generator with a shielded and calibrated output 50uv would be good real life test.
4. I dont remember saying anything about the "marker" but it is standard test you should perform. I wanted to make sure you addressed the high G2 voltage which was not normal before moving on to anything else. The Marker is the Crystal Calibrator that you turn on with the Mic Gain control. If you can get a good strong marker signal it proves your active components Q1, Q2, RIF mixer are all good and problem is in Ant Relay or RF attenuator, or Bad Connector 3 on the RF board or bad input components just down stream of TP-1. I have a RF board on bench now that had bad L1 choke in broadcast band high pass filter that was shunting the weak RF signal to ground.
5. Very good that you were able to adjust VR-3 and set RF1 to 3.6vdc and now you have normal G2 AGC voltage range with RF gain control. At first with the high voltage on G2 I thought you may have had problem on audio board. Very odd that RF1 would be out of adjustment by that extreme amount? Hopefully it will stay in spec.

So -- Now I would perform the "marker" test and see if you get marker signal thru. If you get good signal then turn maker off and inject 14.200 into coax connector and follow the signal path with your schematic to see where you loose it. Antenna relay contact or bad connector 3 on RF board are two more likely candidates. Terry

> > >
> > > If the IP current is 220ma with HV at 760VDC yet you only see approximately 10 watts output then I would look at the antenna change over relay located at the bottom of the final unit PC board, the relay terminals may be carbon coated. You said the meter switch set to RF indicates full scale which tells me either the RF pot on the rear panel is set wrong or the RF pot is set properly and the final amplifier through the PI Network is producing full output but that RF output is not appearing at the rear panel's SO-239 antenna connector. The RF goes through the T/R relay but the RF pot is "before" the T/R relay.
> > >
> > > If the T/R relay is causing your low RF output, I believe the tuning of the PLATE and LOAD controls would not be "normal". The IP dip and LOAD peak RF output adjustments would not results in normal indications because the output of the PI Network is not seeing an impedance load that is within the range of the PI Network (50 to 75 ohms).

32143. Possible TS-830 Schematic Errors?

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-30 13:25:25 UTC

Topic: 32143 Message: 32143

Gang--Electricians live and die by their Elementary diagrams and Hams depend on their Schematics to understand circuit operation and troubleshoot problems. To that end my large TS-830 is getting pretty dog eared and marked up with voltages, signal levels, notes and corrections.

Could Mike or Gordon or someone look at two areas for me and determine if the schematic is drawn wrong. If drawn wrong, interested members can correct their schematic to reflect actually as-built.

1. RF Board--The resistors and capacitors associated with Gate 1 of
RF amp dual-gate mosfet Q1 are drawn wrong. The bias resistors R10 & R11, and caps C42 & C44 are not connected as shown. I discovered this while troubleshooting RB1 bias.

2. Rectifier Unit Board and Screen Grid Switch S20--The industry standard for relay contacts is to show them in the de-energized state. Either the relay contact of RL-1 (-c switching) is shown wrong or Screen Grid switch position is drawn wrong. I believe the Screen Grid switch should be shown in the "ON" position which would then de-energize the relay and make the contacts correct as shown.

Appreciate a review of this so we can all have accurate tools.

Thanks-Terry K9TW

Hi Terry,
I have found the R-10,R11 C42 and C44 error already in the past.
I believe I also discovered the same issue you found on the rectifier
Board, but my memory forgets that for sure LOL

Gordon--Ok just wanted some one with more experience to confirm what I found. I have a couple more marked on my schematic. Wonder if I should write/draw this up and make a folder for it? Maybe already on our site somewhere. I didnt look. Terry

I have to replace the power switch on my TS-830S, which mean removing the front panel.. and all the knobs.

SO I"m wondering if there's any special tools needed or anything I need to be careful of?

Hi Kent,

No special tools required. I did it recently with my 830. The original owner had fitted a non standard switch.

Pretty easy to do once you have taken front off.

Thanks
Chris, ZL1CDP

I have a TS-820 I acquired from a SK shack cleanout. It is for sale.

The SK was a consumate ham..everything he had was in perfect order..all the time.

That said, I have not benched it yet. I plan to this weekend....My venerable 30 year old TenTec 229 tuner died on me last weekend so I was preoccupied with replacing it. This weekend the TS-820 will be gone through and made sure it is 100%.

For you youngsters in the world of Kenwood...this was considered one of the best HF transceivers in its day. People still speak of its receive qualities with hushed reverance.

http://www.eham.net/reviews/detail/154

This is not the S model....no digi dial...that was the only difference between the TS-820 and the TS-820S. (If you can find a digi kit, it is real easy to convert...1 hour of time, if memory serves me.)

I am in Reno, Nevada, email address is WA6RKN@..., telephone number is 1 775 746-2733, Weekdays only, 8 to 5, Pacific time. (My business phone.) Feel free to call and talk about the radio. Oh, and it includes the manual, no mic, built in power supply.

Price is negotible. I would like $3000.00 for it. (I wish!) Seriously, I am thinking if it is up to snuff, About $300.00, CONUS. No out of country sales unless you have a verifiable U.S. shipping address.

I am not excited about shipping the radio..it is HEAVY, but will let THEUPS STORE do the honors if that is your wish. They are pricy but do a good job.

If you would like pictures, let me know, and I will accommodate your request, but it might take a couple of days to open it up for the 'shoot'.

Bob:

Was the TS-34/AP used as a substitute for the display unit in radars such as the APS-6 during troubleshooting? Is that what it is designed to do? I note that it has a SO-239 input jack and is designed to use the same kind of hood as on the WWII airborne radars.

Thanks,

Robert

Hi Jeramy,

I did some adjustments, but no improvement. It is interesting, that on 7 MHz & 14 MHZ bands display shows 2 MHz less (i.e. 5 & 12 MHz respectively) while at 21 MHz bands and above it shows 6 MHz more (i.e. 27 MHz and 2_ it is a blank on second digit).

Any thoughts about that?

On 7 MHz for example however, display shows 5 MHz, at 14 MHz band it shows 12 MHz, on 21 MHz band shows 19 MHz. On 3.5 MHz and 1.8 MHz display shows correct frequency.
